How do crop calendars work in CLM?

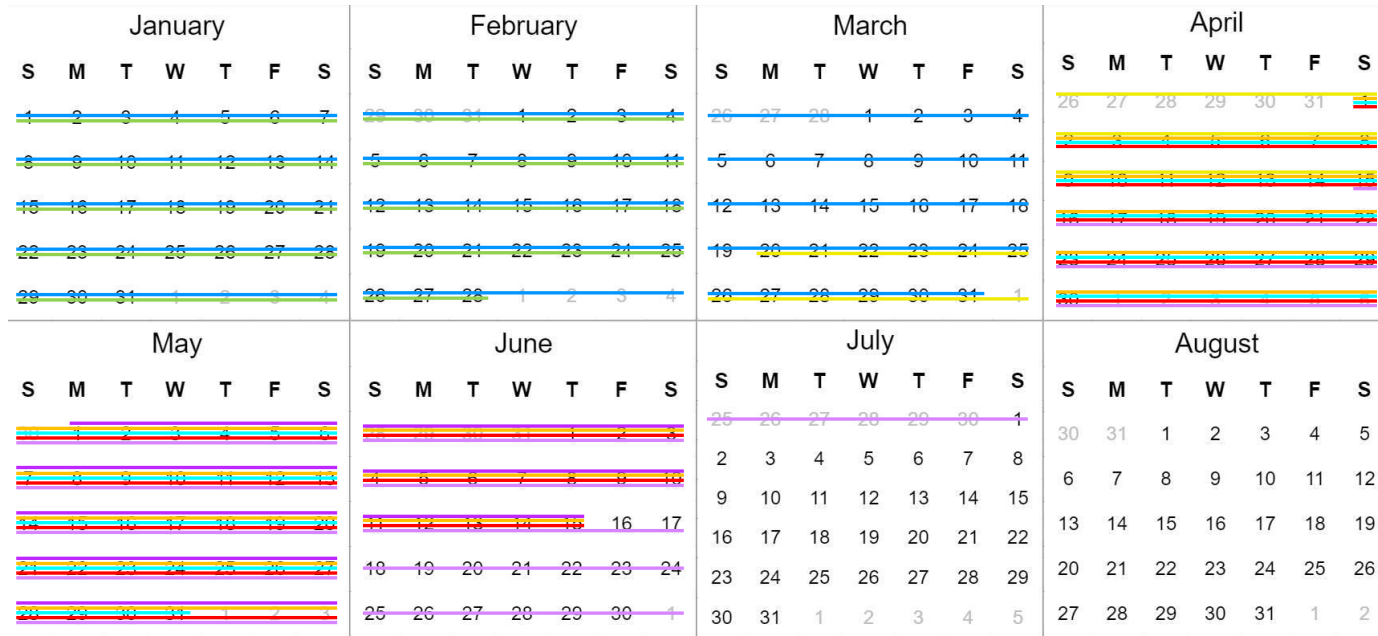

Sowing date \longrightarrow ~~Harvest date~~
 “Windows”

Maturity requirement

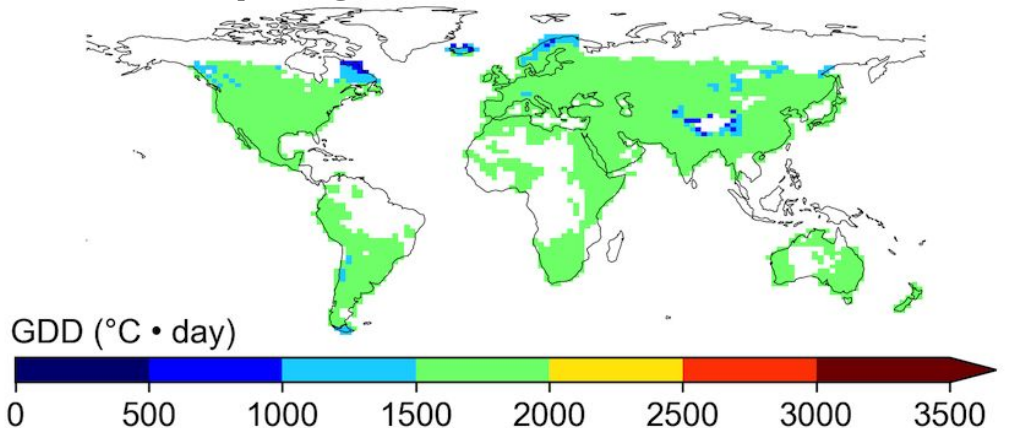

How warm has it been, for how long?

“**Growing degree-days**”

Northern Hemisphere

Rainfed spring wheat

How do crop calendars work in CLM?

Advantages

- Sowing windows allow some geographic and interannual **variation**
- Long-term **shifts** with climate change possible for both sowing date and harvest requirements

Disadvantages

- Sowing windows based only on **temperature**
 - Moisture more important in some places
- **Limited variation possible** in harvest requirements
 - Tropics need more GDDs to mature
- Generally: Parameterized for **North American** planting decisions & cultivars
- Sowing window **boundaries** may limit future adaptation

So you've developed a better system?

No :) I made it so CLM can read **externally-specified sowing dates and maturity requirements.**

Advantages

- Use **arbitrary crop calendar algorithms** without needing to code them into CLM
- Participate in **model intercomparisons** that require use of standard calendars
- **Force with observations**, compare to built-in crop calendars

Disadvantages

- Inputs **not necessarily prognostic** (and so far they aren't)

Well then what are you presenting?

Use observation-based crop calendars to evaluate:

- **Where and how** CLM's system might be improved
- **How much** improvement might result

Advantages

- Use **arbitrary crop calendar algorithms** without needing to code them into CLM
- Participate in **model intercomparisons** that require use of standard calendars
- **Force with observations**, compare to built-in crop calendars

Disadvantages

- Inputs **not necessarily prognostic** (and so far they aren't)

GGCMI Phase 3 crop calendar

Jonas Jägermeyr; Christoph Müller; Sara Minoli; Deepak Ray; Stefan Siebert

The new crop calendar for GGCMI Phase 3 is a composite product merging various observational data sources. It provides in each 0.5° land grid cell the planting day and maturity day for 18 different crops, separating rainfed and irrigated systems. Grid cells outside of currently cultivated areas are spatially extrapolated and original data gap-filled. This crop calendar version only provide **static growing periods, i.e., the multi-year average** estimates. We only specify a single growing season per crop and grid cell, and no crop rotations are considered. However, for wheat and rice we provide data for a second season with separate crop calendars for winter and spring wheat, and two separate main rice growing seasons.

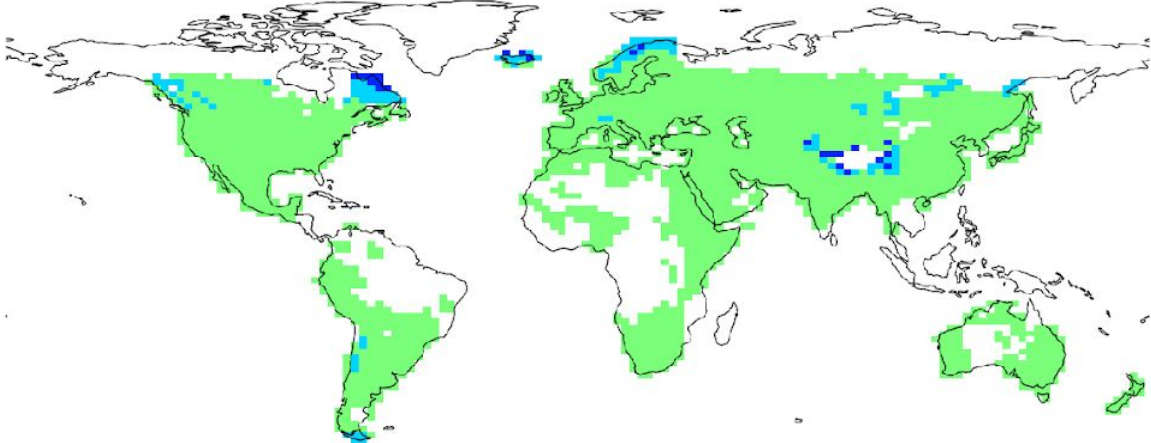

Experimental setup

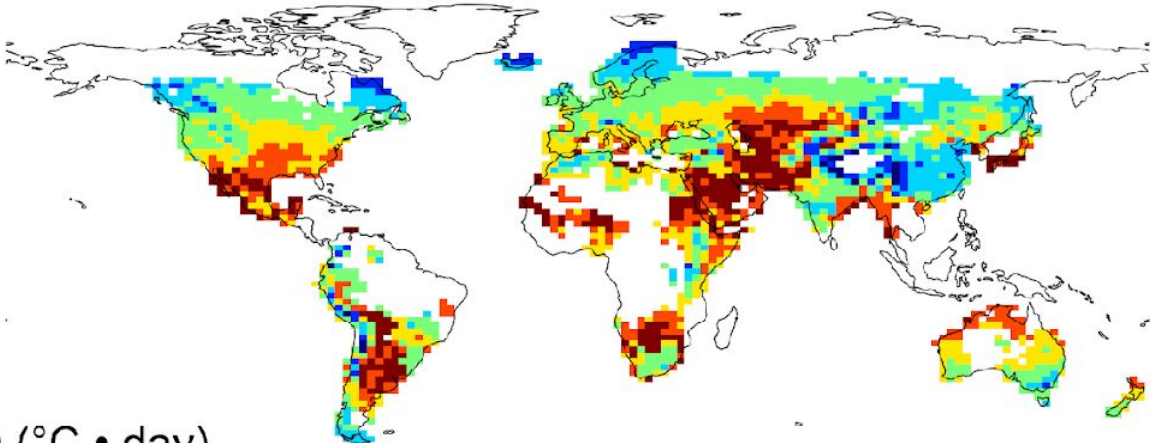

- CLM5.0
- Unlimited irrigation
- “2-degree” resolution
- Analysis: 1980–2009 growing seasons

Rainfed spring wheat: Maturity requirements

CLM Default (range 571–1700)

Prescribed Calendars (range 16–3852)

GDD (°C · day)

Zonal changes

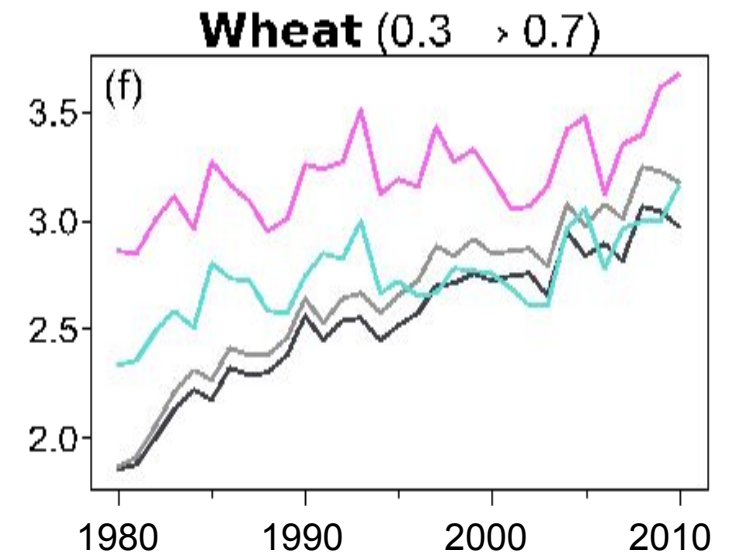

Global yield

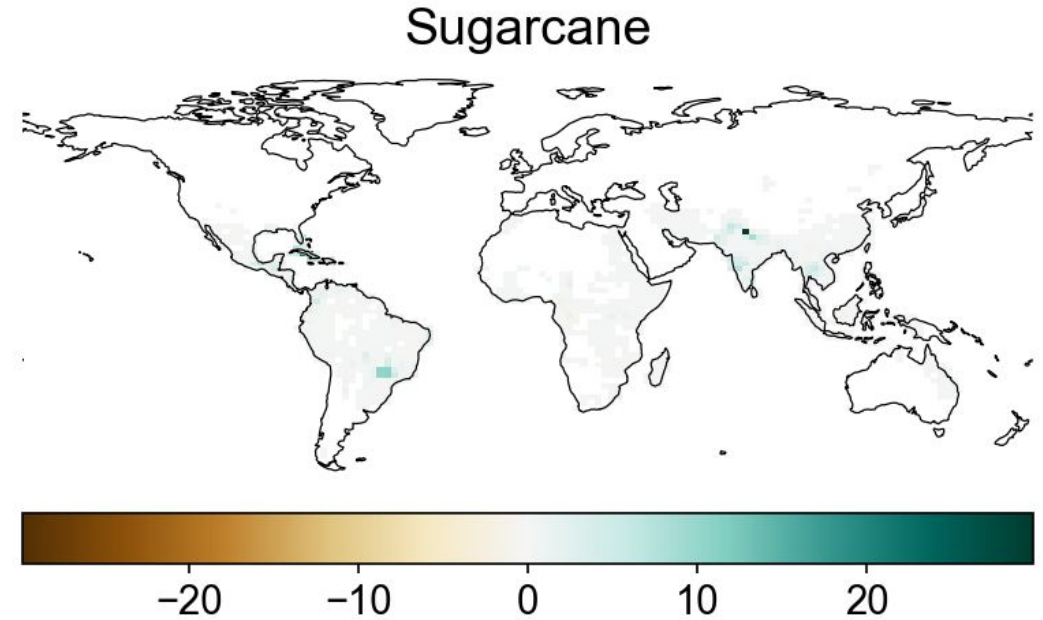

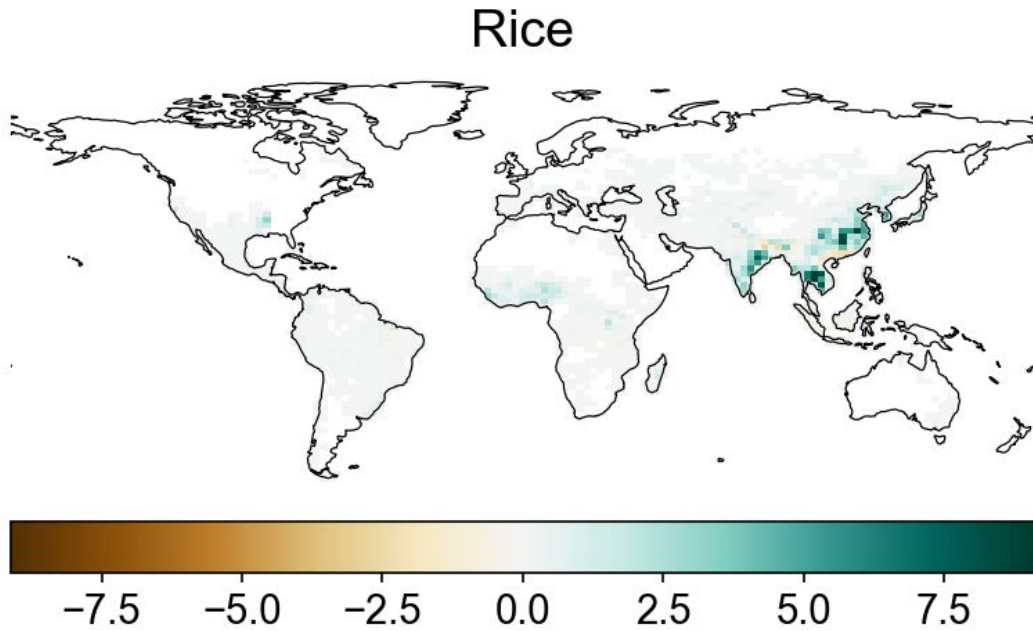

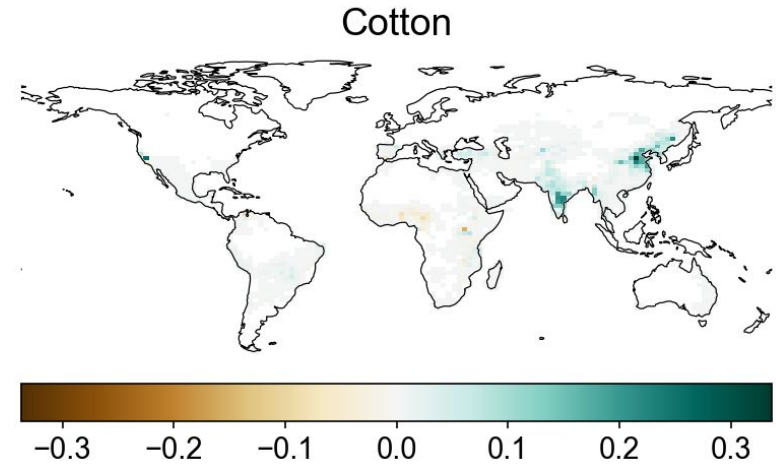

Global yield (t/ha)

Global yield (t/ha)

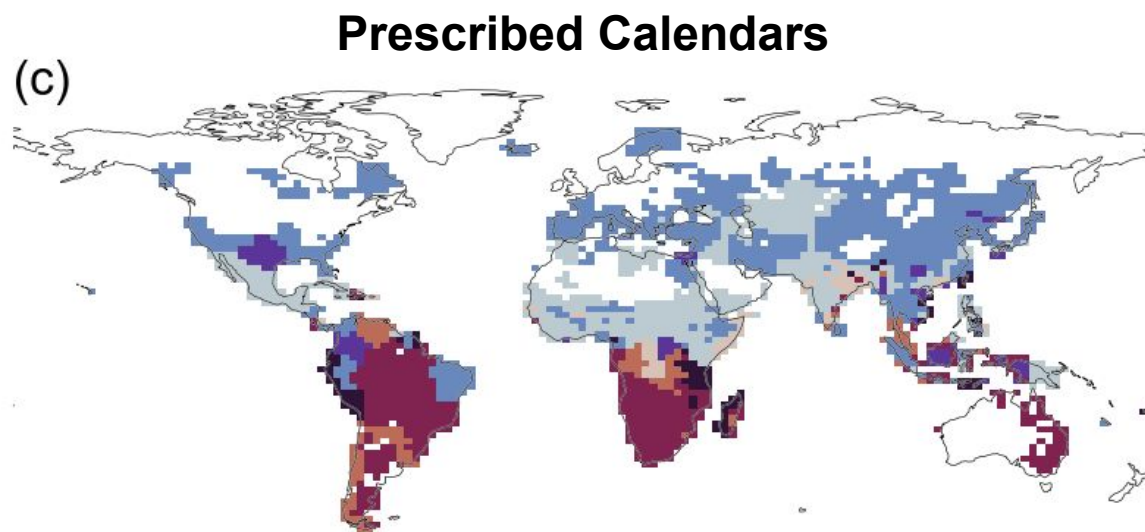

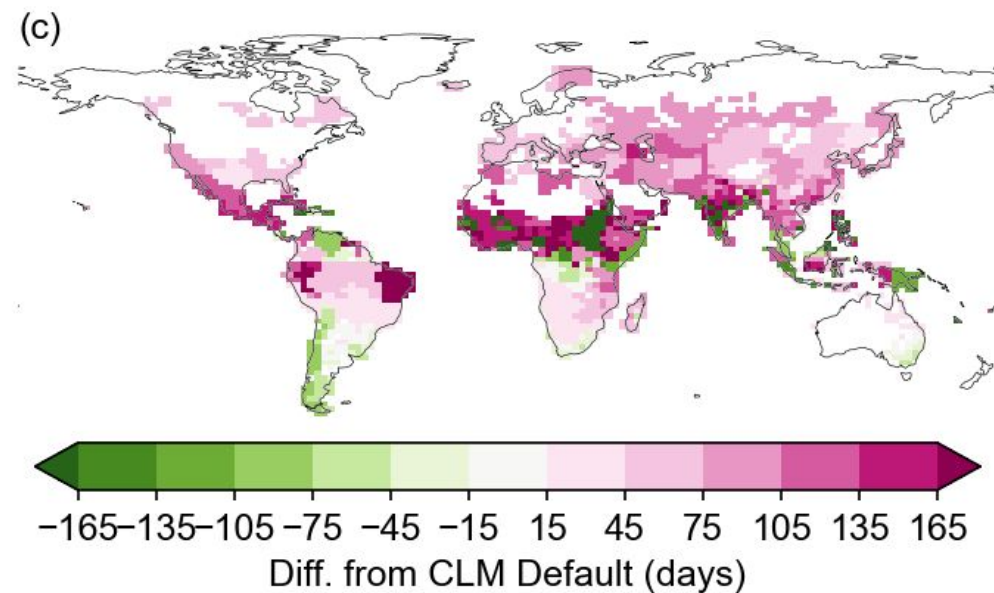

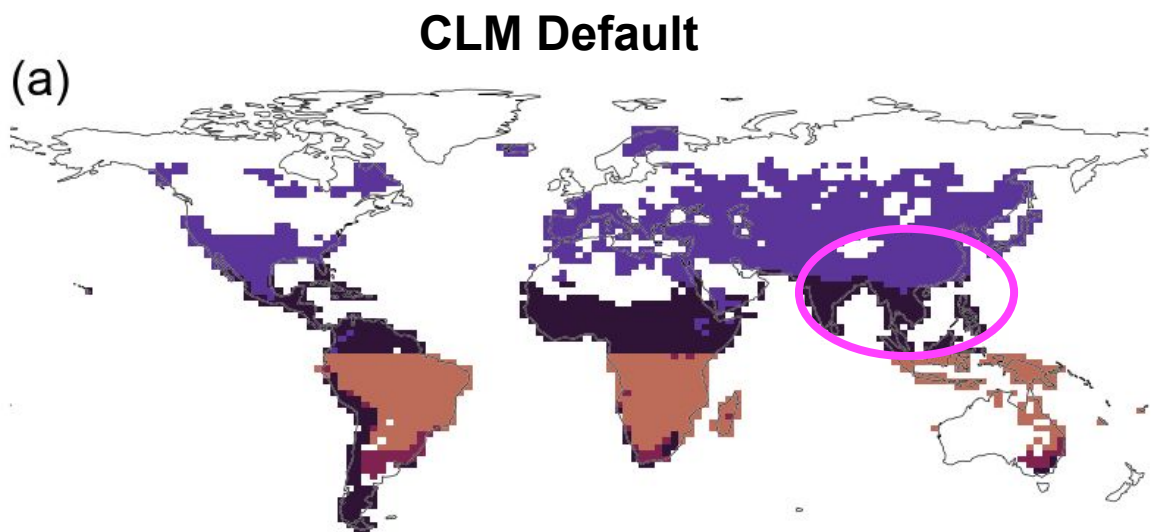

Regional yield difference (Mt)

Prescribed Calendars minus CLM Default

Rice

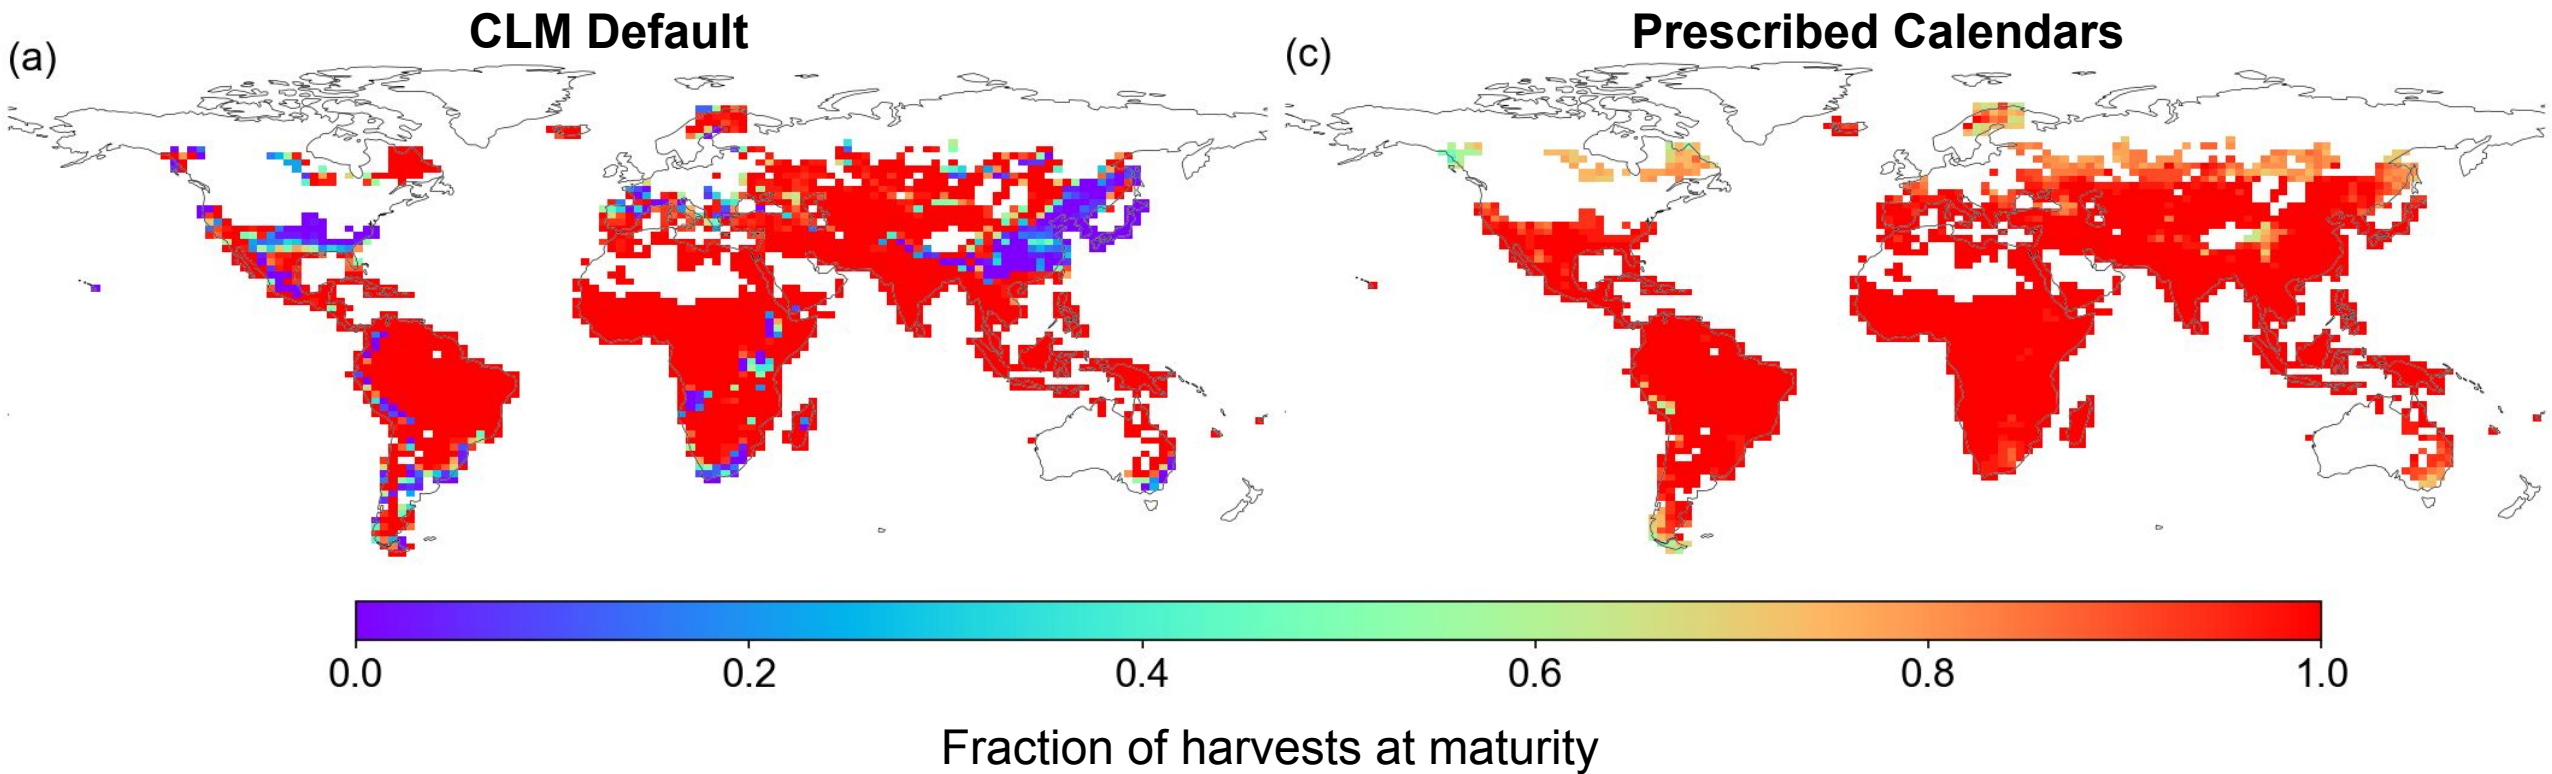

Sowing date caused most of the change.

Rice

Sowing date caused most of the change.

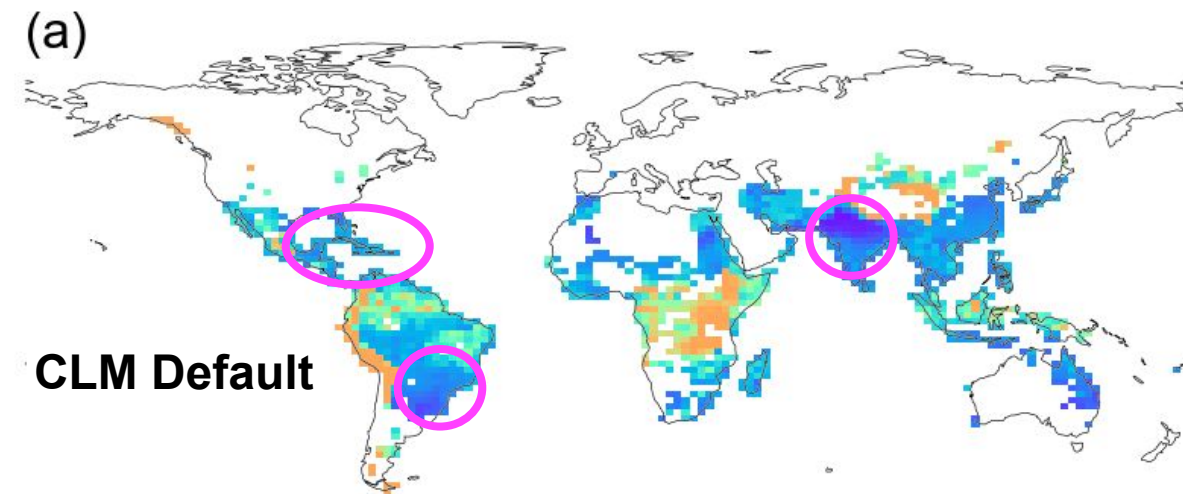

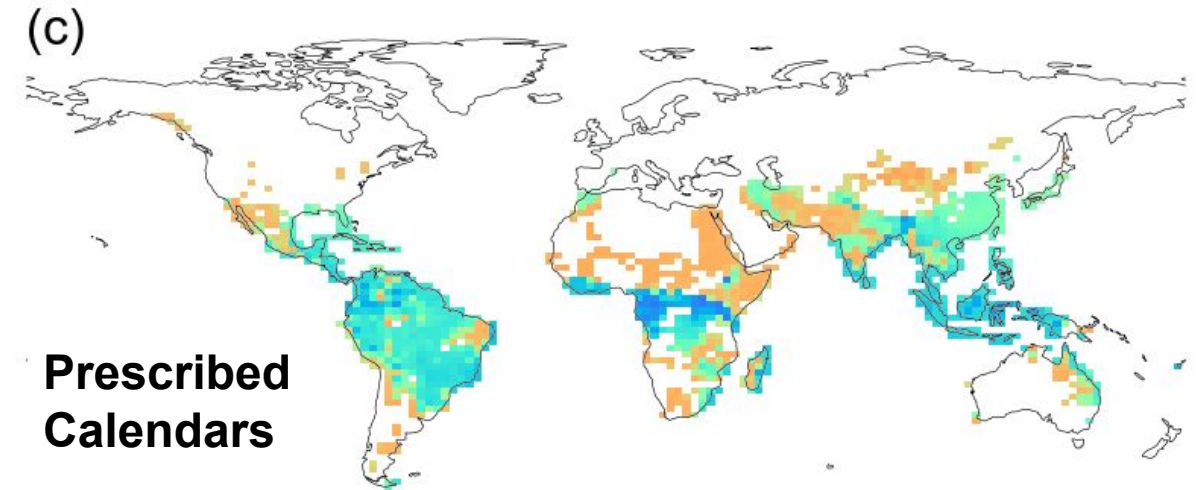

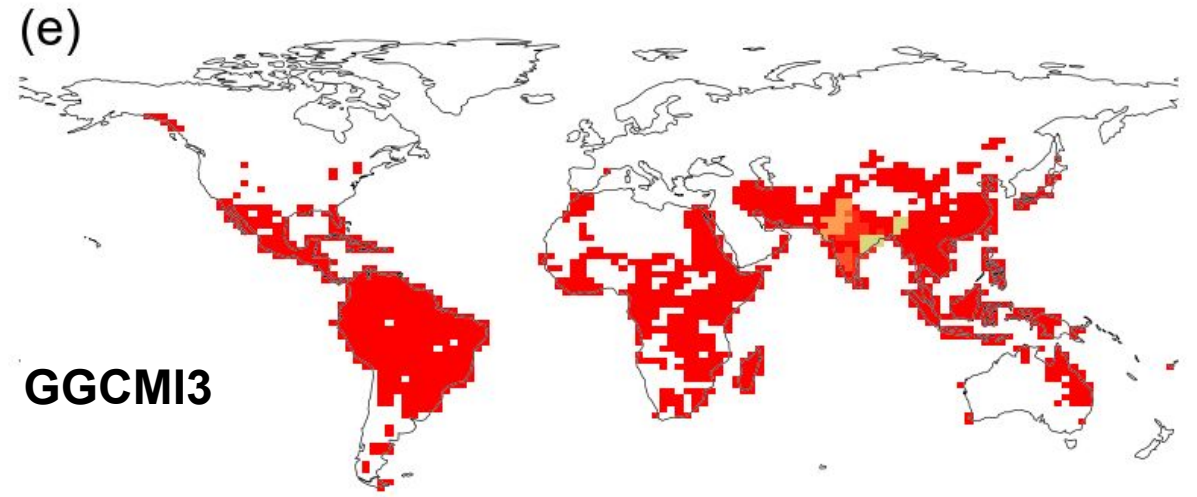

CLM Default has many **failed seasons**.

Sugarcane

Plants **matured too fast.**

Max. length 300 days is still limiting.

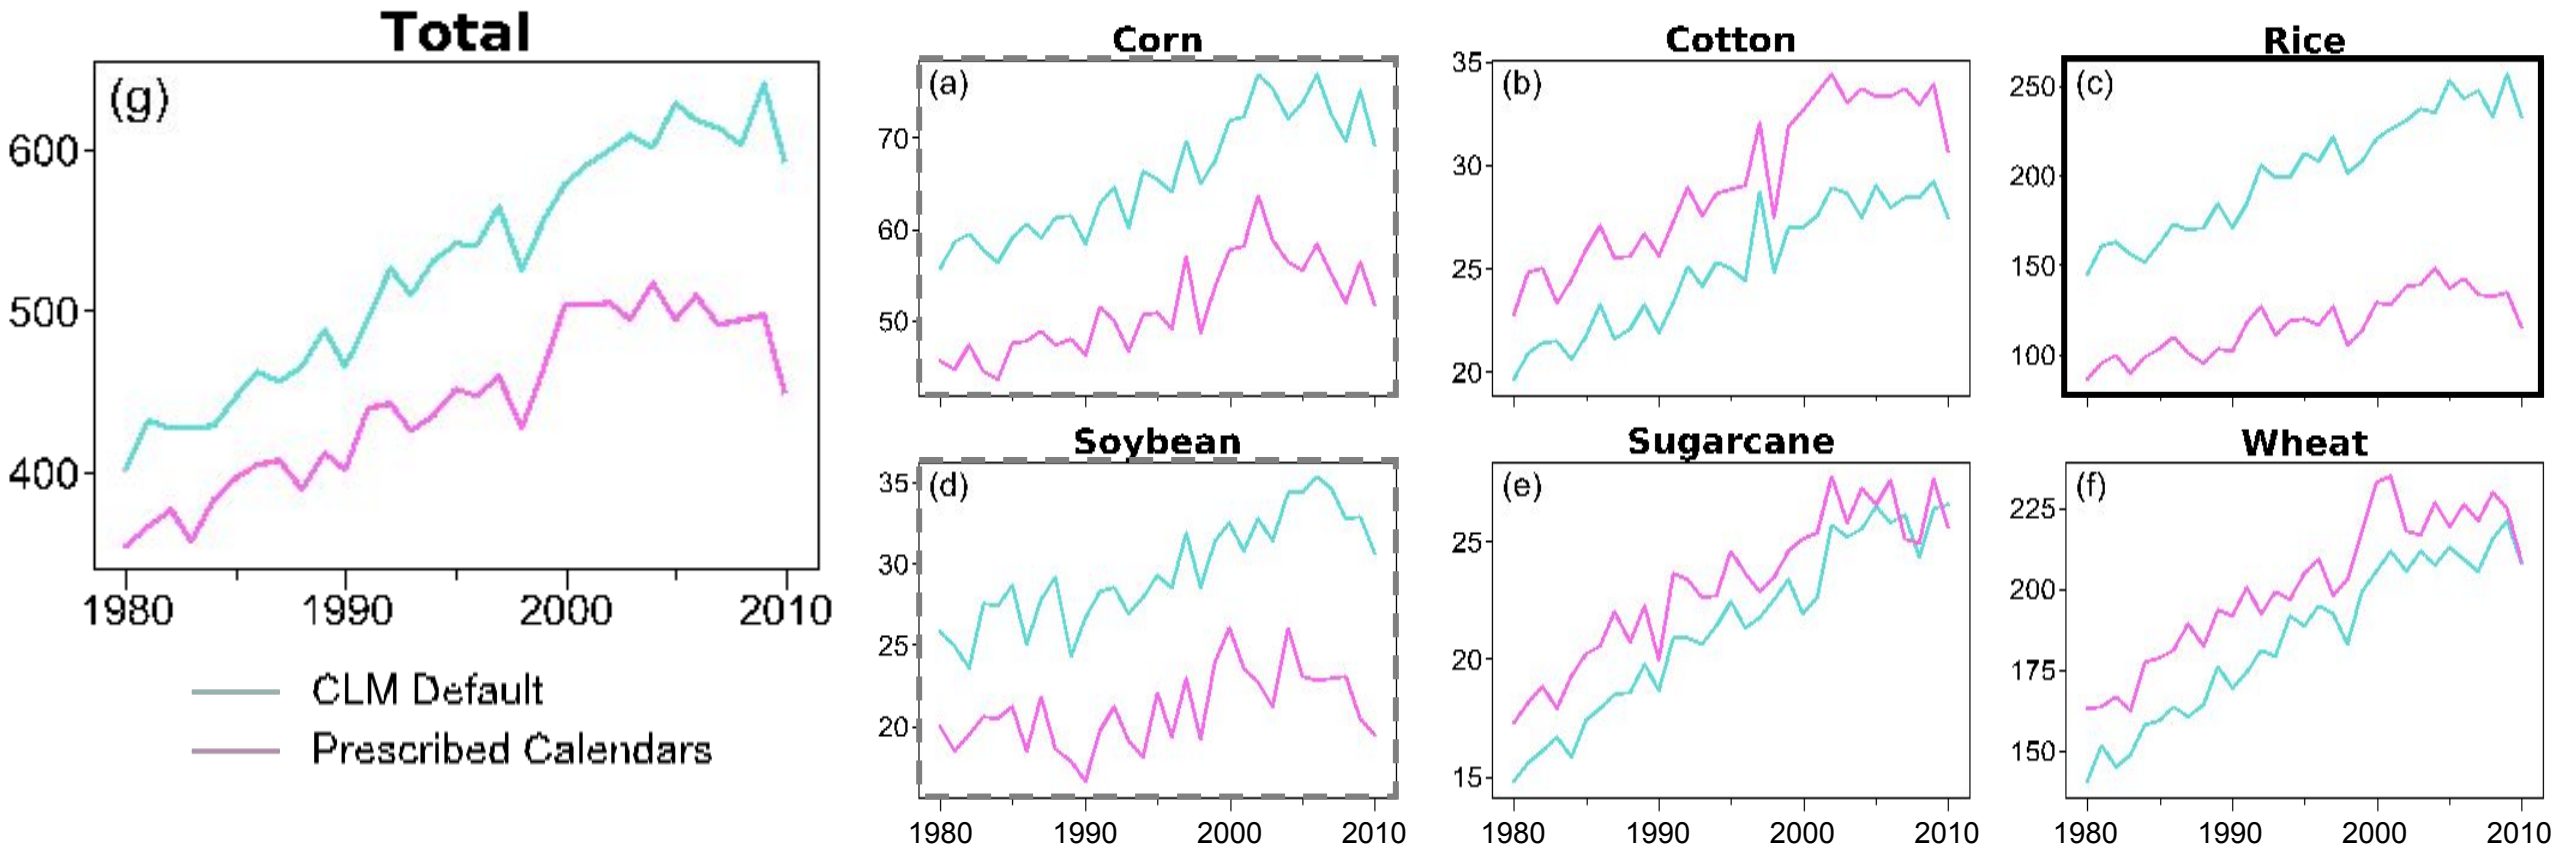

Irrigation (km³)

Less irrigation with Prescribed Calendars.

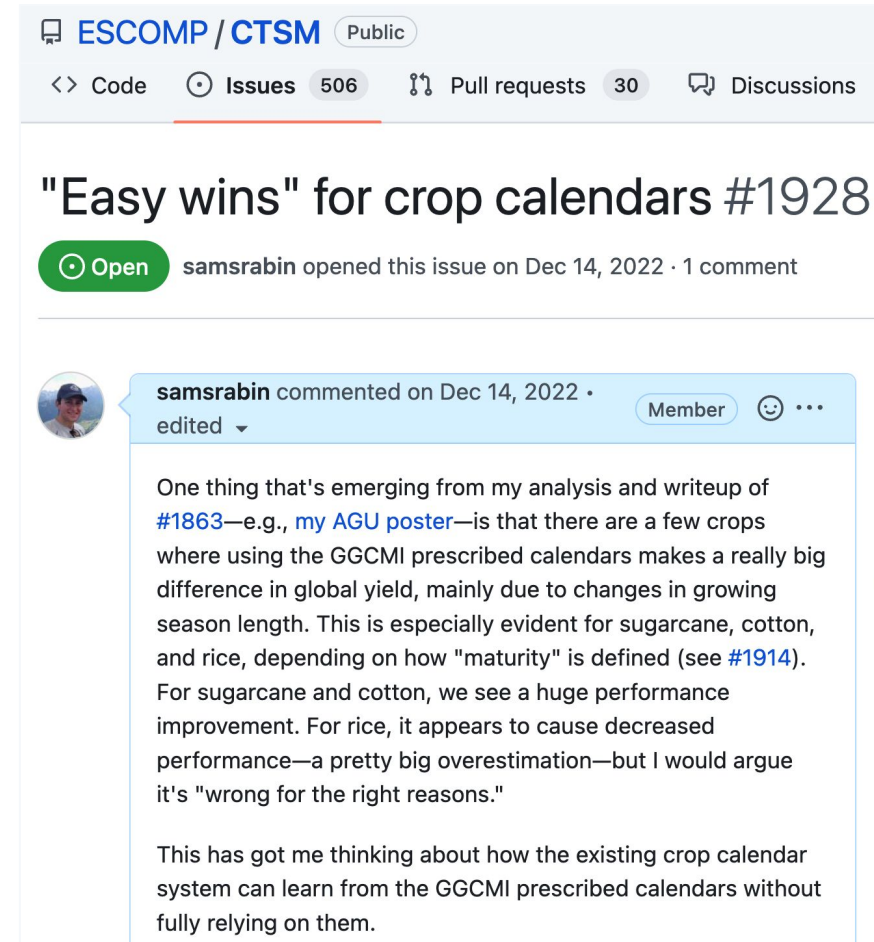

Apparently the **wrong direction...**

But **more realistic irrigation** techniques (Yao et al., 2022) give an *overestimate*.

How can we improve CLM?

- Gridcell-specific **sowing dates**; windows centered on GGCM13 values
- Use **maturity requirements** derived from GGCM13
 - Scale based on decadal climate averages
- Replace **maximum growing season length** parameter with more flexible behavior

"Easy wins" for crop calendars #1928

One thing that's emerging from my analysis and writeup of [#1863](#)—e.g., [my AGU poster](#)—is that there are a few crops where using the GGCM1 prescribed calendars makes a really big difference in global yield, mainly due to changes in growing season length. This is especially evident for sugarcane, cotton, and rice, depending on how "maturity" is defined (see [#1914](#)). For sugarcane and cotton, we see a huge performance improvement. For rice, it appears to cause decreased performance—a pretty big overestimation—but I would argue it's "wrong for the right reasons."

This has got me thinking about how the existing crop calendar system can learn from the GGCM1 prescribed calendars without fully relying on them.

Thank you!
