Outline

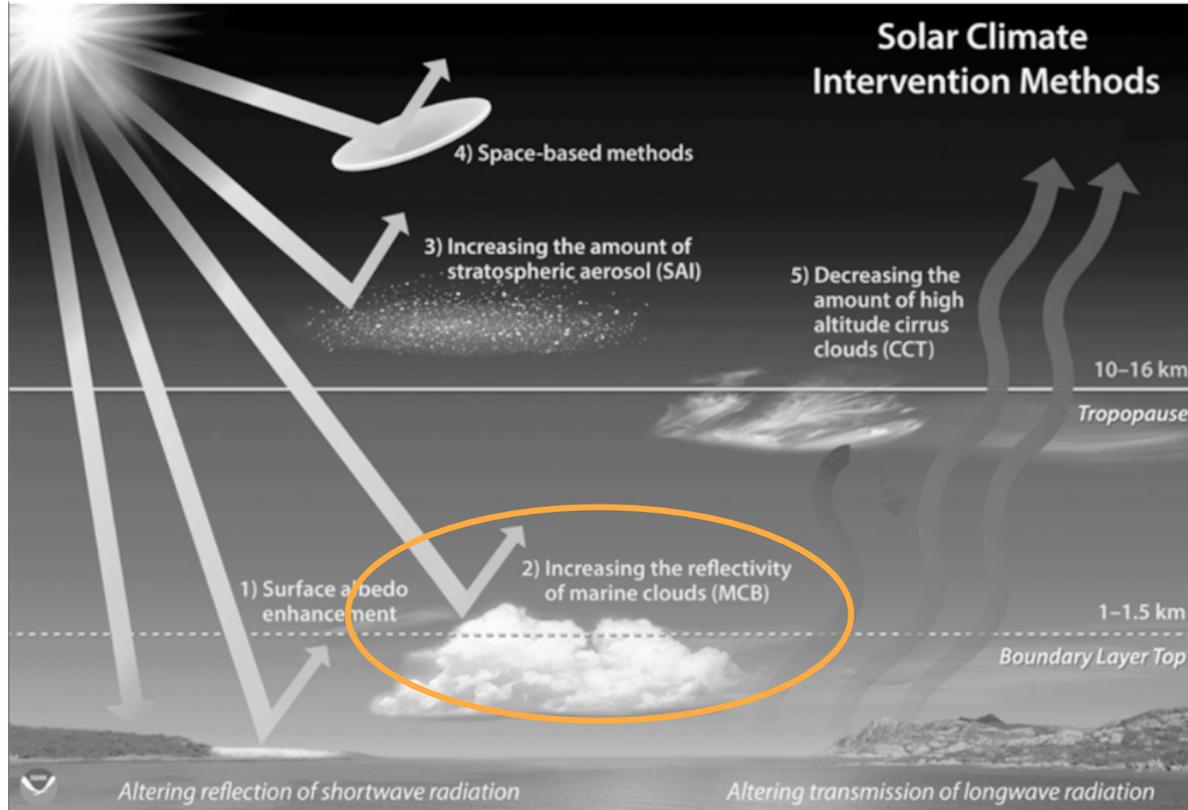

- Motivation
- Experimental Setup
- Global Impacts
- Atmospheric and Surface Energy Budget Impacts
- Snow, Sea Ice, & Ocean Impacts
- Ecosystem Impacts
- Conclusions and Next Steps

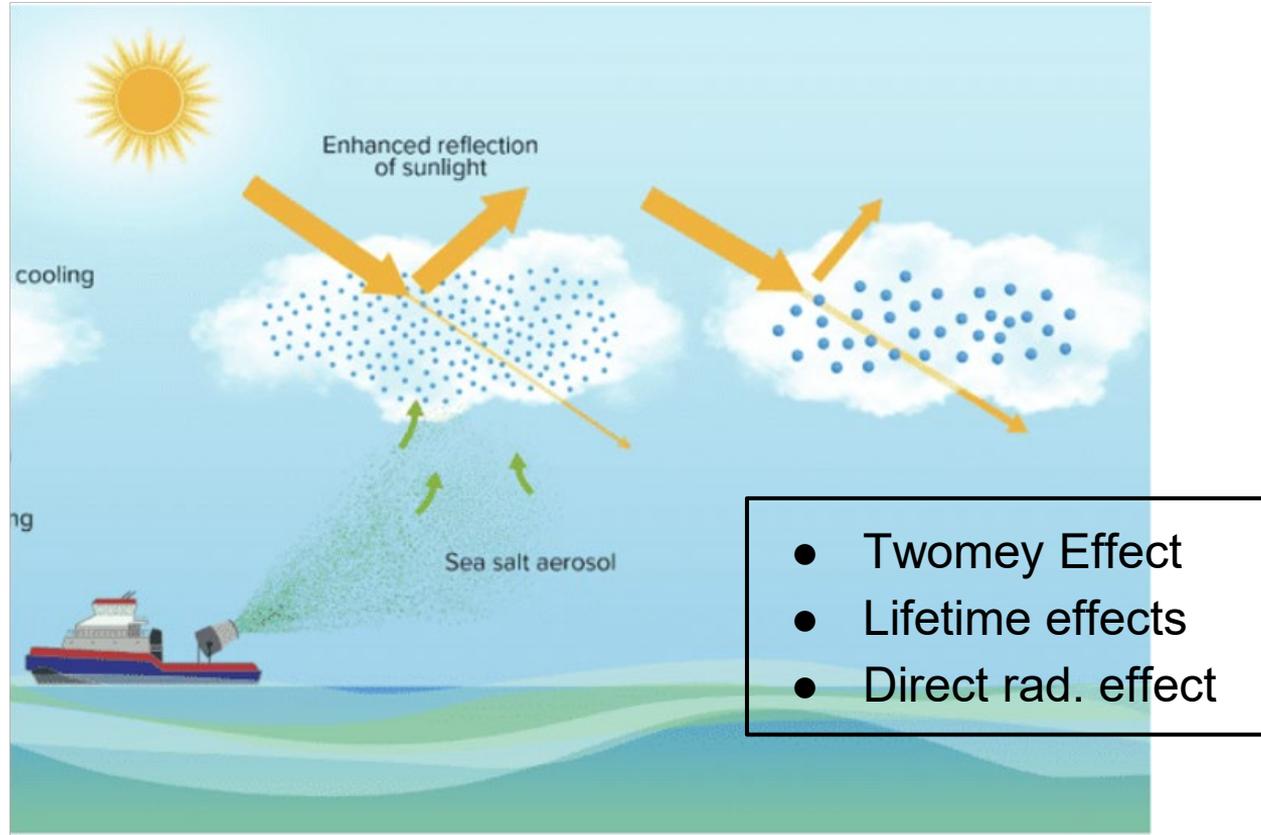

Introduction: Climate Intervention

“Solar radiation
modification”

“Solar geoengineering”

Introduction: Climate Intervention

Experimental setup: model

- CESM2-CAM6 simulations

Moderate warming

- SSP3-7.0 scenario

Near future; similar timeline to other MCB/SAI simulations

- Model years 2035-2070

Smoothed biomass burning

- smb, less-melt, 4p2z modifications

Ocean Biogeochemistry

Indirectly increase sea ice albedo

- 5 baseline ensemble members

Cloud droplet number concentration ($\#/cm^3$)

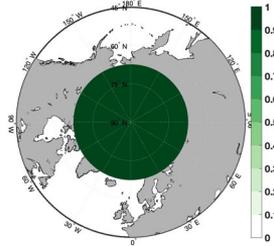

- 9 MCB simulations

Perturb N_d in low clouds in select grid cells

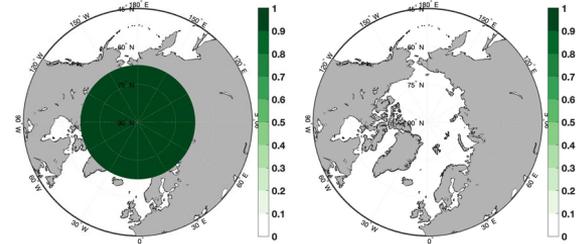

Experimental setup: seeding maps

“ANN”
Year-round seeding
All grid cells $>67^\circ\text{N}$

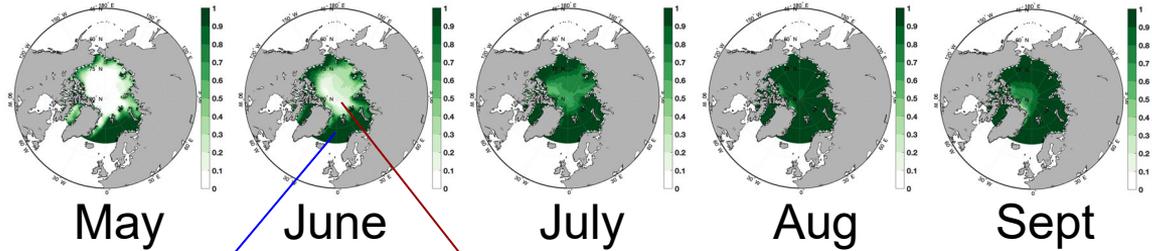

“MJJAS”
Summer-only seeding
All grid cells $>67^\circ\text{N}$

May-Sept

Oct-Apr

“Dynamic Mask”
Summer-only seeding, $>67^\circ\text{N}$;
exclude SIC $\geq 90\%$, land $\geq 50\%$
Change mask each timestep

Dark green: seeded
most/all of the time

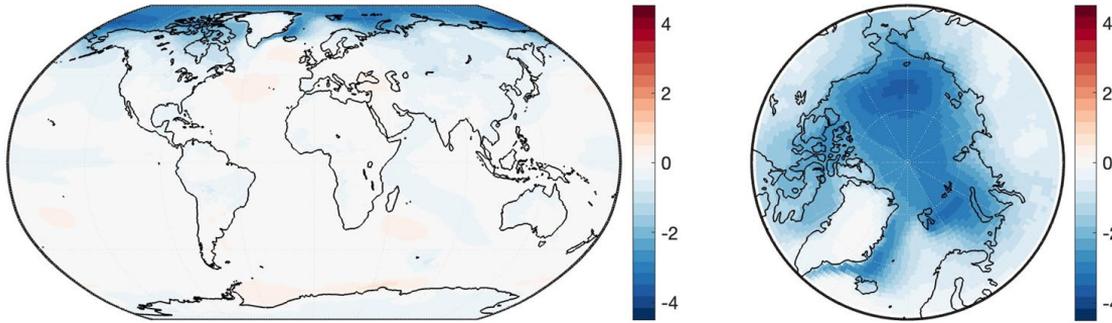

Light green/white:
seeded less often

Each strategy: $N_d \rightarrow 100, 200, 400 \text{ \#/cm}^3$ simulations

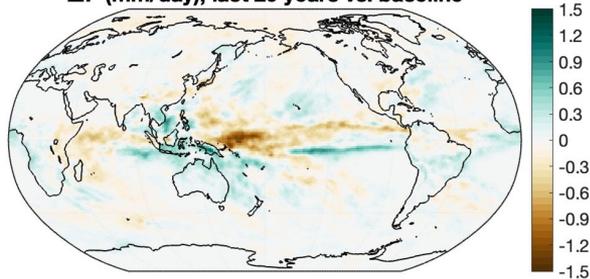

How much does this cool the planet in CESM2?

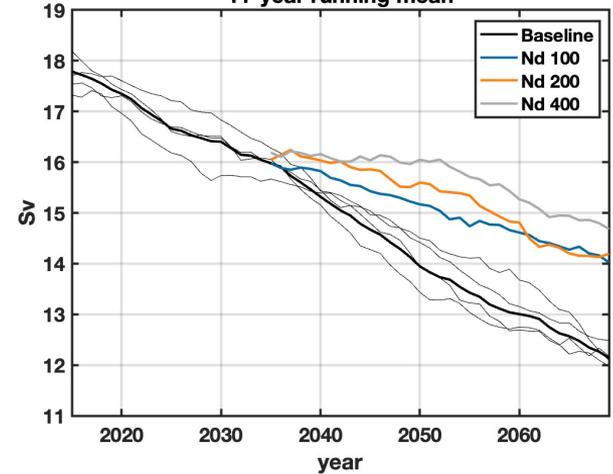

MCB, Dynamic Mask, $N_d = 200 \text{ cm}^{-3}$
 ΔT ($^{\circ}\text{C}$), last 20 years vs. baseline

MCB, Dynamic Mask, $N_d = 200 \text{ cm}^{-3}$
 ΔP (mm/day), last 20 years vs. baseline

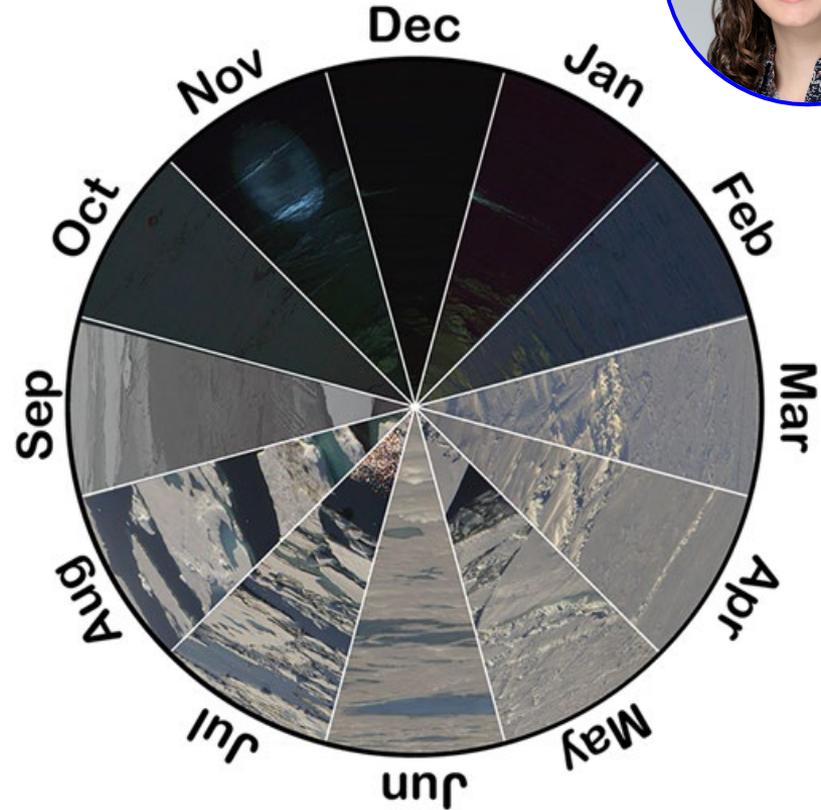

AMOC strength (max ψ below 500m @ 26.5 $^{\circ}$ N)
11-year running mean

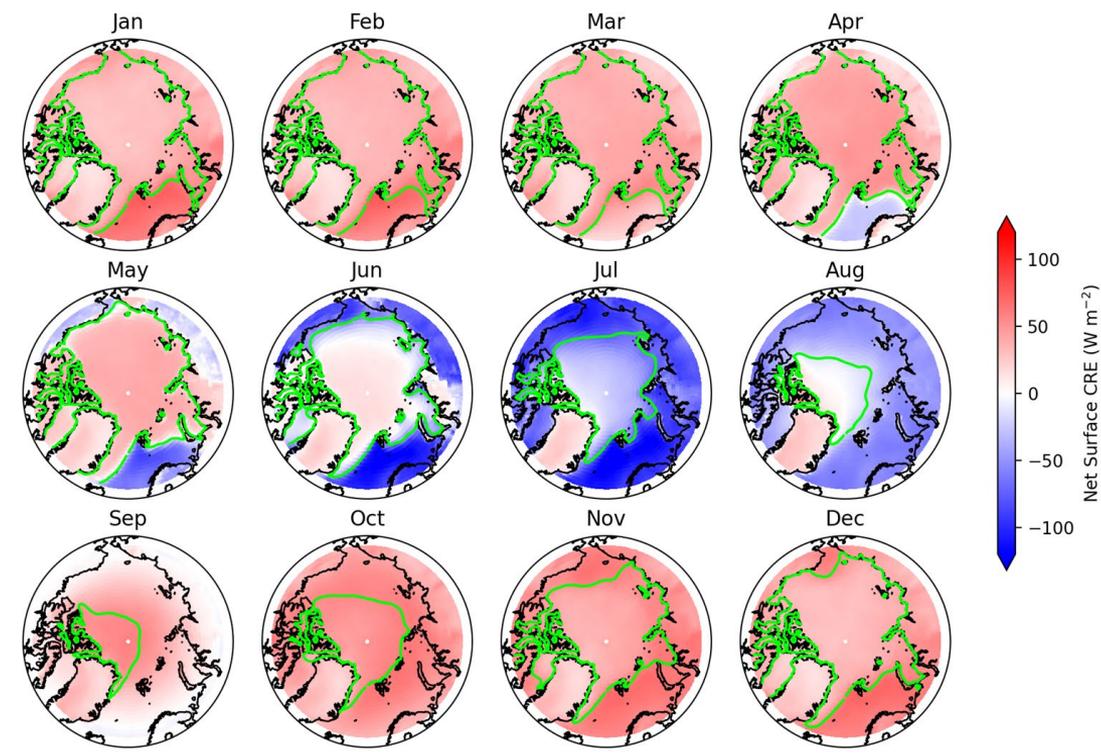

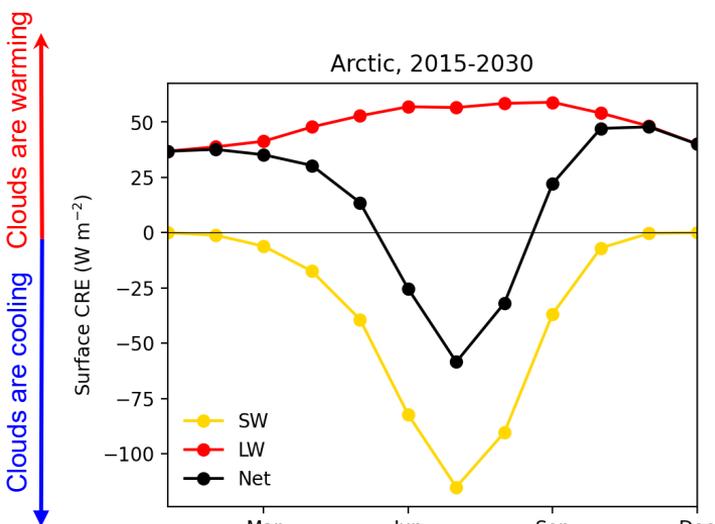

Outline

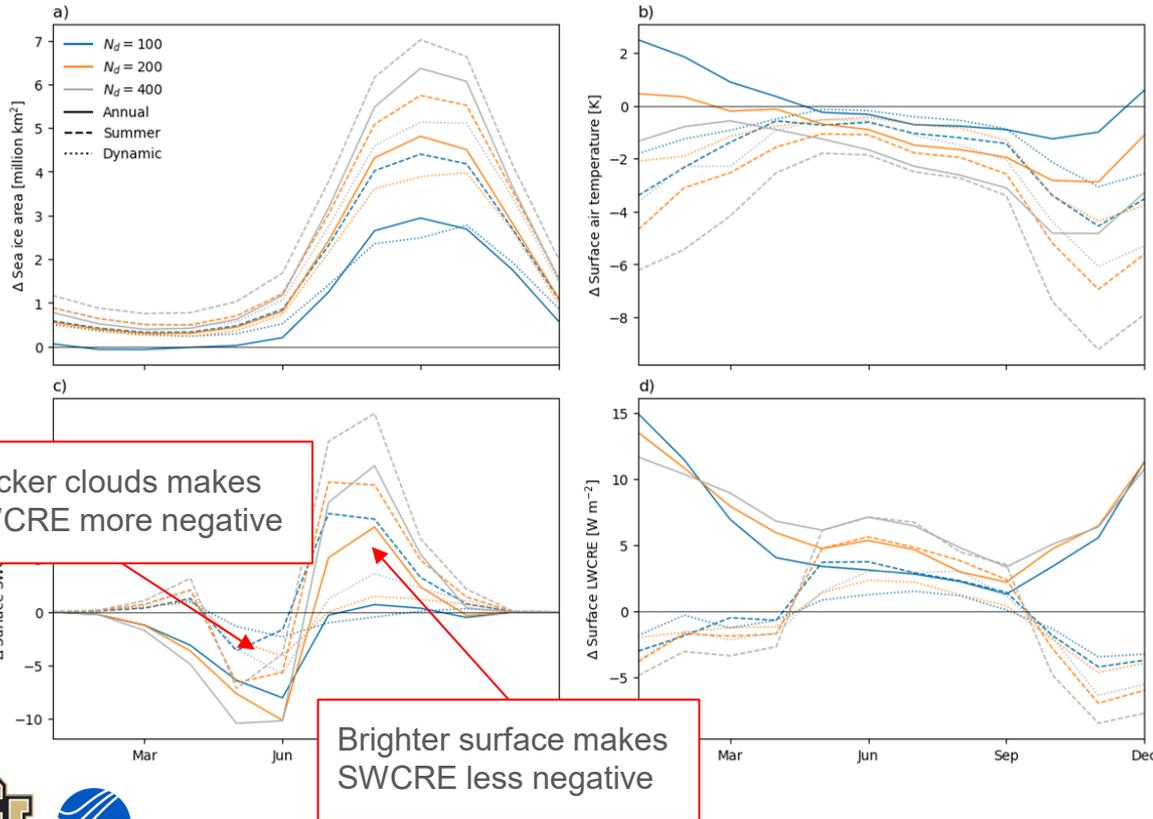

- Motivation
- Experimental Setup
- Global Impacts
- Atmospheric and Surface Energy Budget Impacts
- Snow, Sea Ice, & Ocean Impacts
- Ecosystem Impacts
- Conclusions and Next Steps

Clouds currently cool the Arctic only in summer, mostly over open water and MIZ

Seasonality of changes

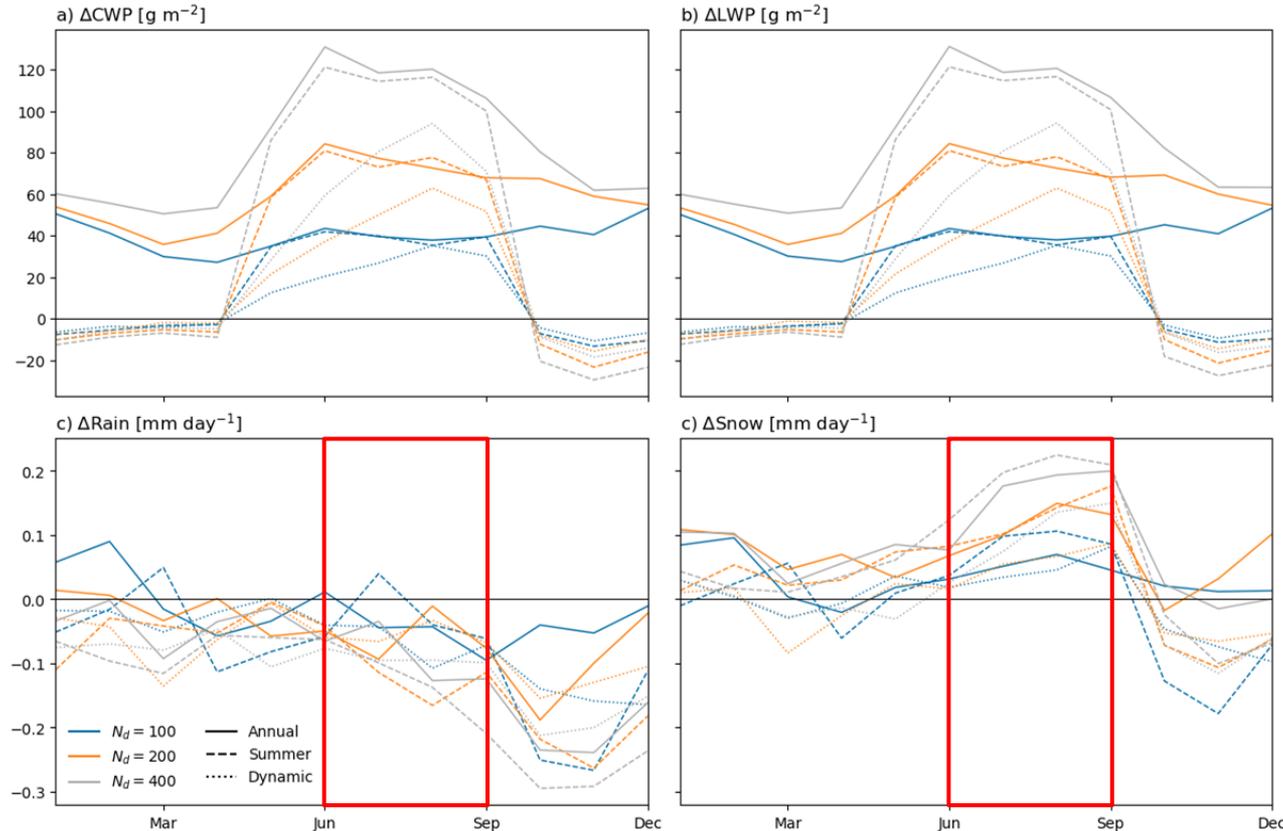

- Largest changes in sea ice area in summer/fall.
- Summer-only perturbations eliminate unwanted winter warming via LW effects.
- Surface cover, not just cloud cover, influence CRE.

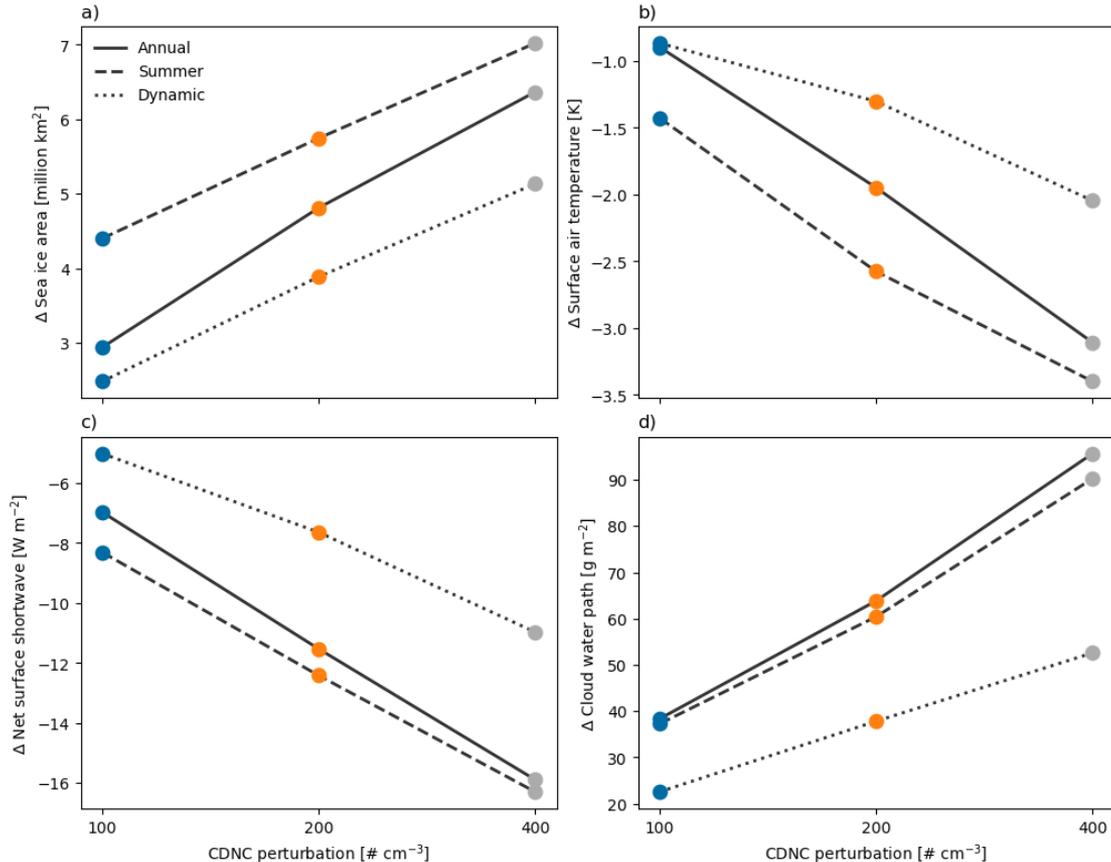

Changes in cloud and precipitation amount

- Nearly all changes in cloud water are in liquid phase.
- Shift in summer precipitation from rain to snow.
- Less total precipitation in fall.

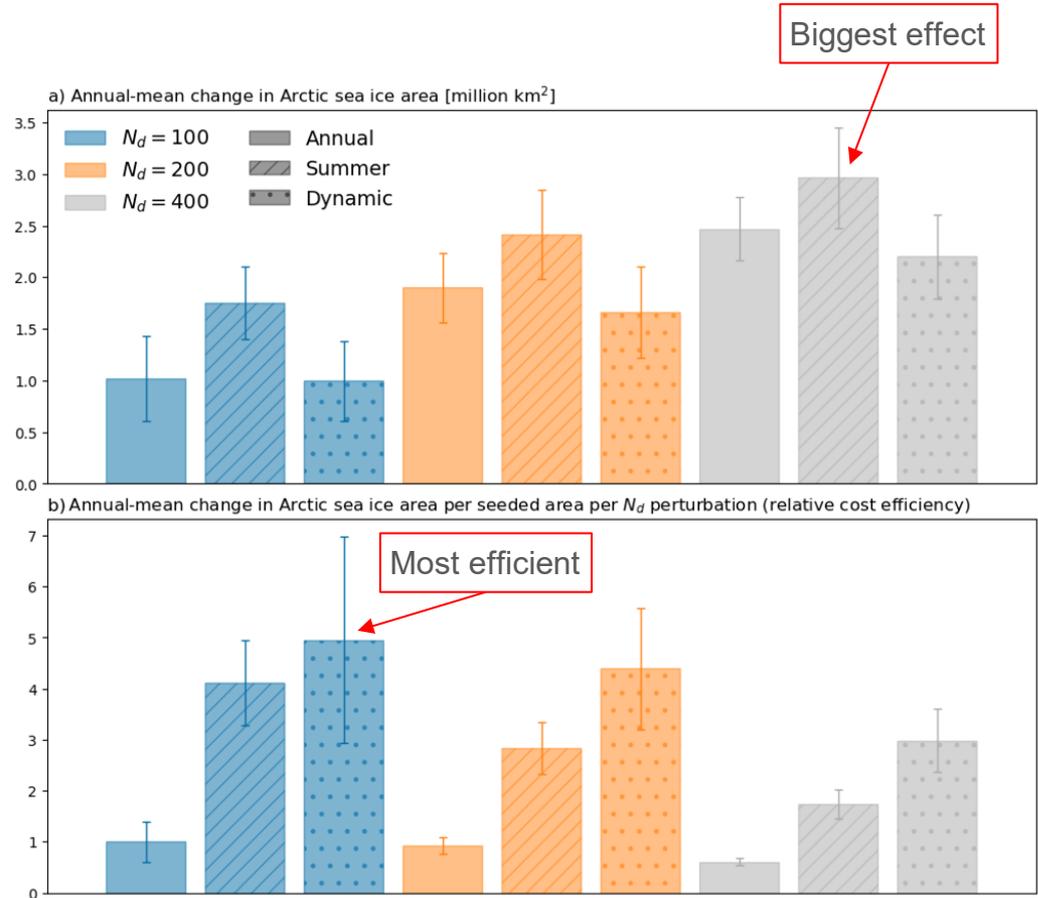

Many responses are linear for *Nd* doubling

Effect vs. efficiency

Summer-only, dynamic
(SIC<90) perturbation is most
efficient.

**Efficiency = change in Arctic
sea ice area per total seeding
(area * Nd)*

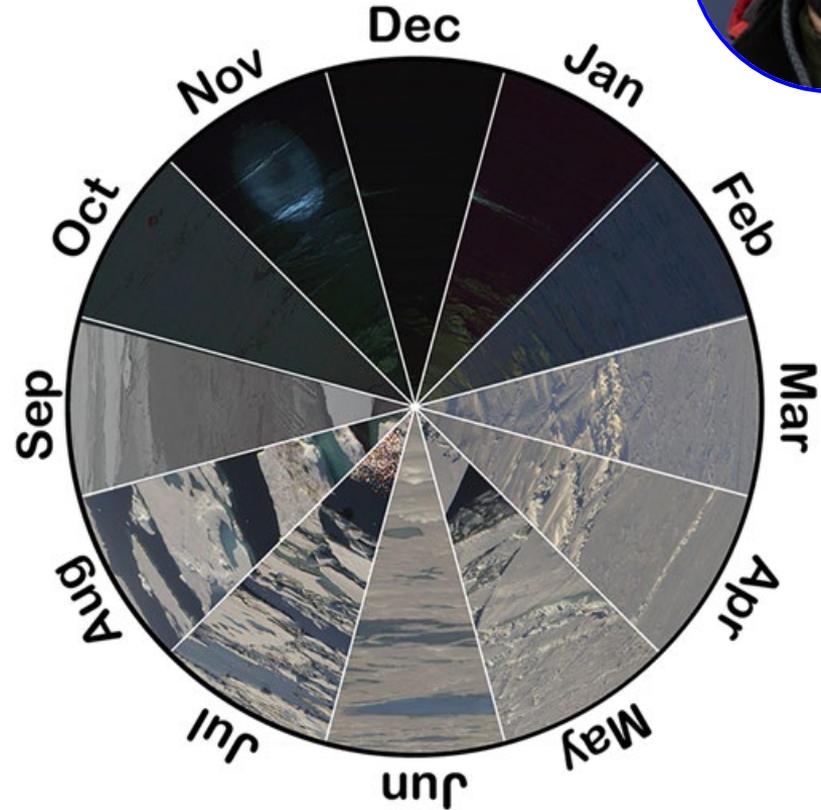

Atmosphere & Radiation Takeaways

1. Cloud perturbations are most effective during summer months
2. Perturbations are most efficient over open water
3. Cooling shifts precipitation from rain to snow during summer months, but decreases total precipitation during fall
4. Many climate variables respond linearly to doubling of N_d

Annual Cycle of North Hemisphere Snow and Sea Ice

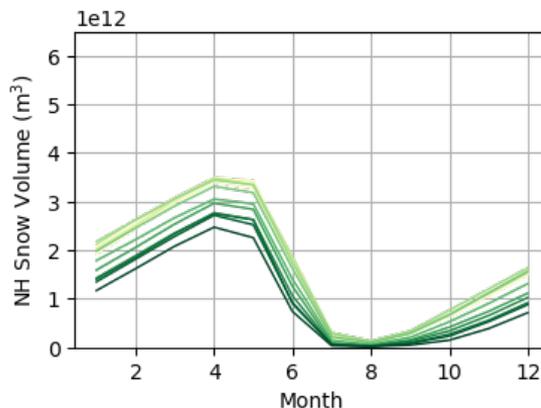

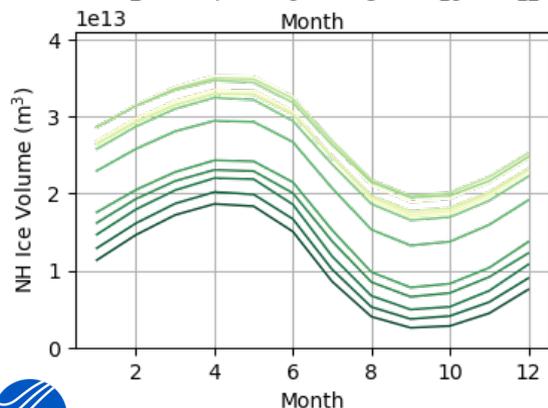

Annual Cycle of North Hemisphere Snow and Sea Ice

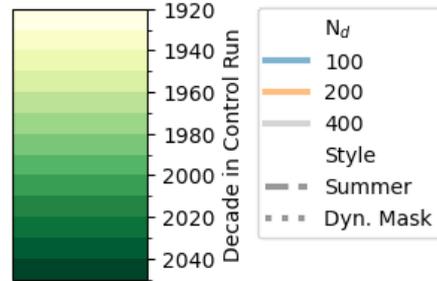

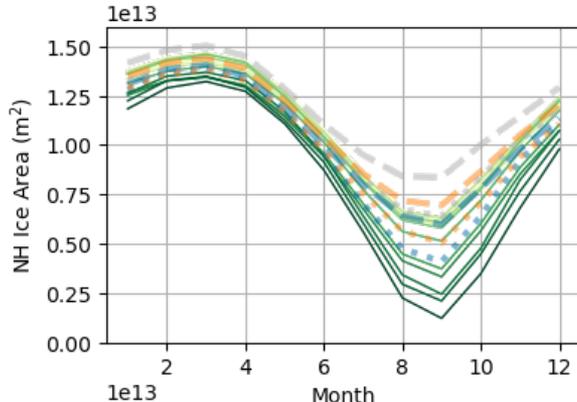

Key Points:

1. N_d 100 & 200 perturbations return ice area to historical

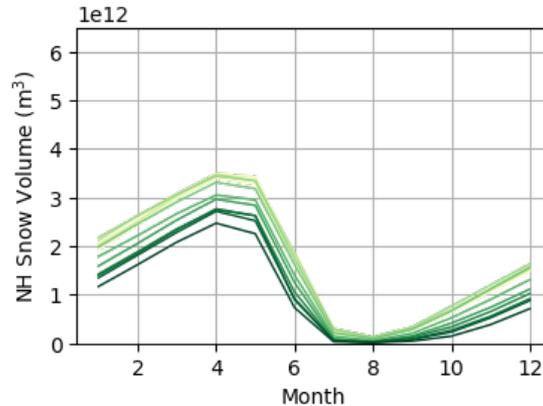

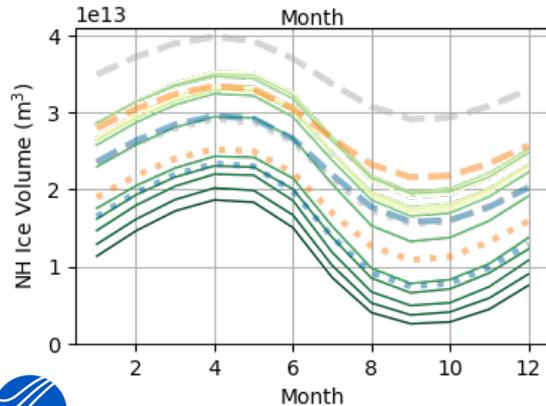

Annual Cycle of North Hemisphere Snow and Sea Ice

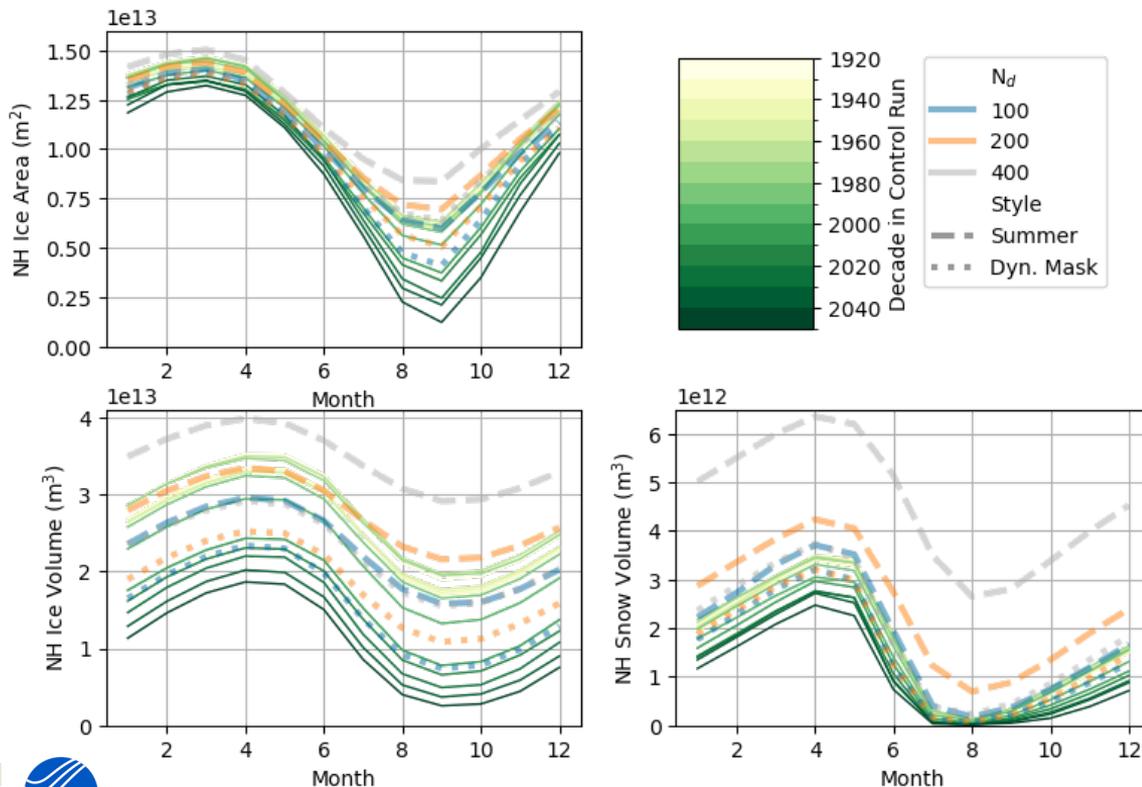

Key Points:

1. N_d 100 & 200 perturbations return ice area to historical
2. Seasonal cycle of ice volume is dampened relative to historical

Annual Cycle of North Hemisphere Snow and Sea Ice

Key Points:

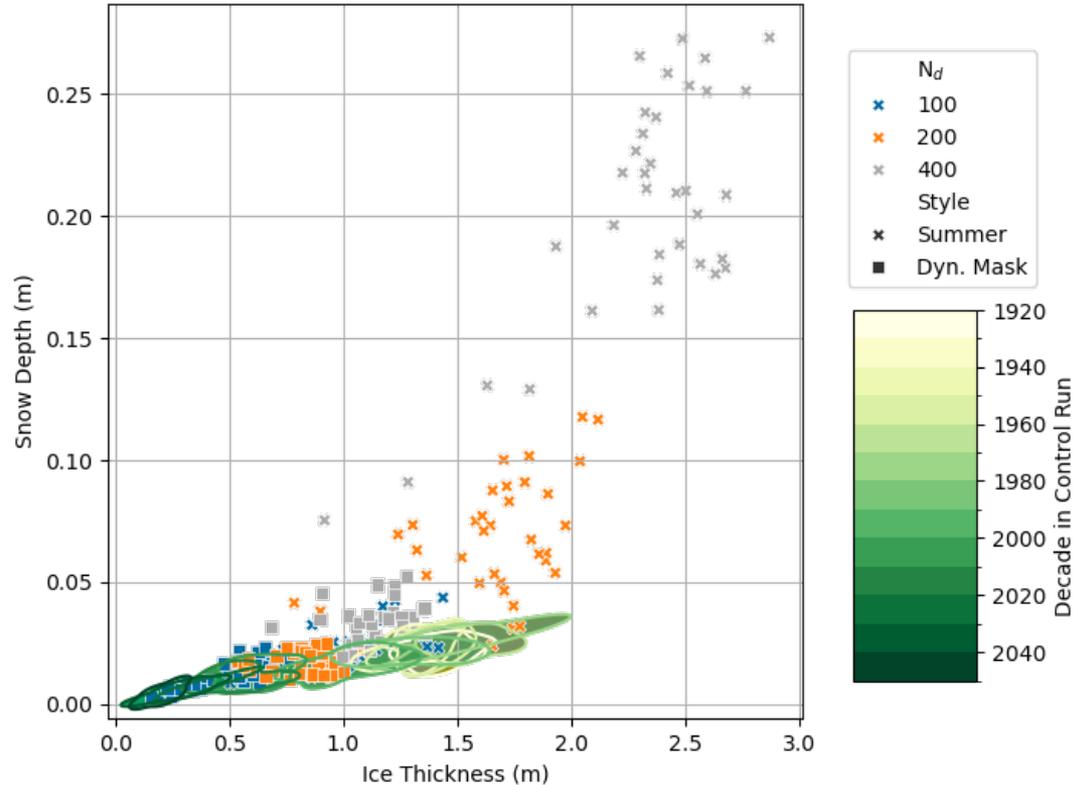

1. N_d 100 & 200 perturbations return ice area to historical
2. Seasonal cycle of ice volume is dampened relative to historical
3. N_d 200 & 400 produce unprecedented perennial snowpacks

Historically Unprecedented Sept. Snow and Ice States

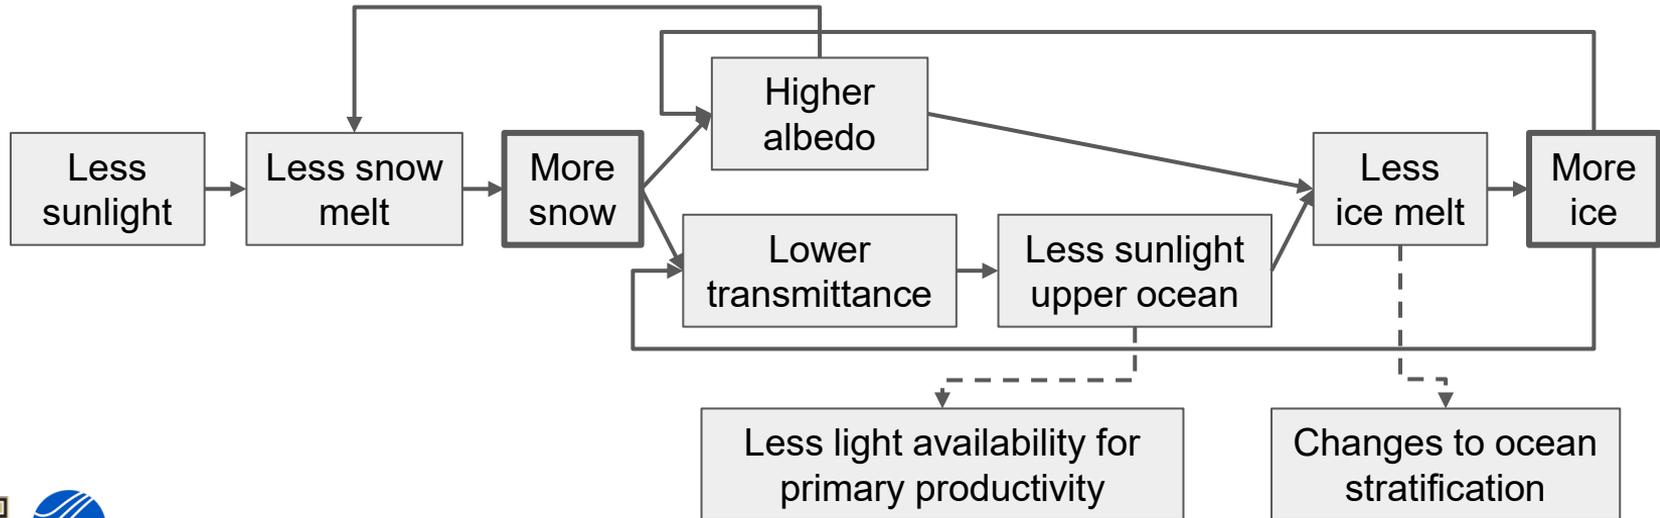

The N_d 200 & 400 Summer perturbations and the 400 Dynamic Mask produce snow and sea ice states with historically unprecedented deep snow.

Figure shows 1940s in the perturbations for the ocean north of 67N. Differences are most dramatic in Central Arctic (not shown)

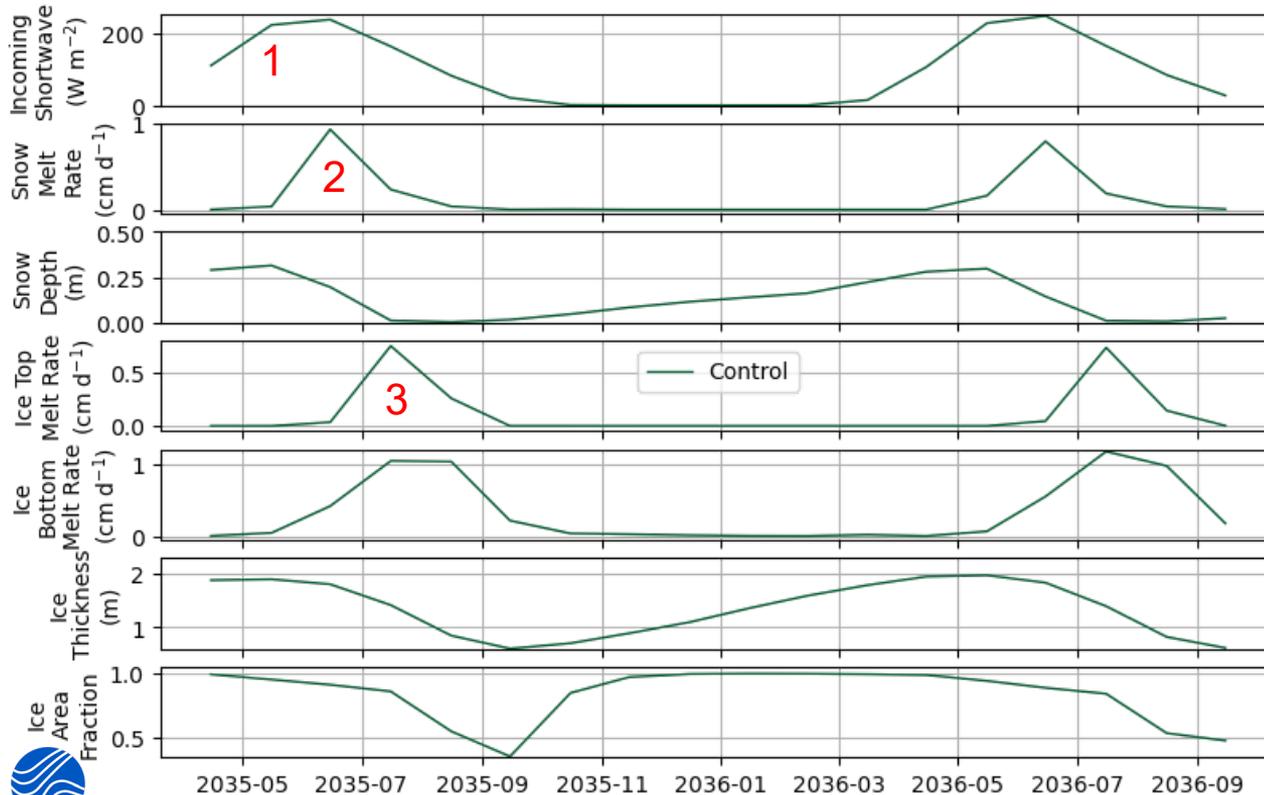

Hypothesis

A reduction in incoming sunlight decreases snow melt rates, kicking off a positive feedback that results in historically unprecedented summertime snow conditions (high), light availability in the upper ocean (low), and changes to upper ocean stratification.

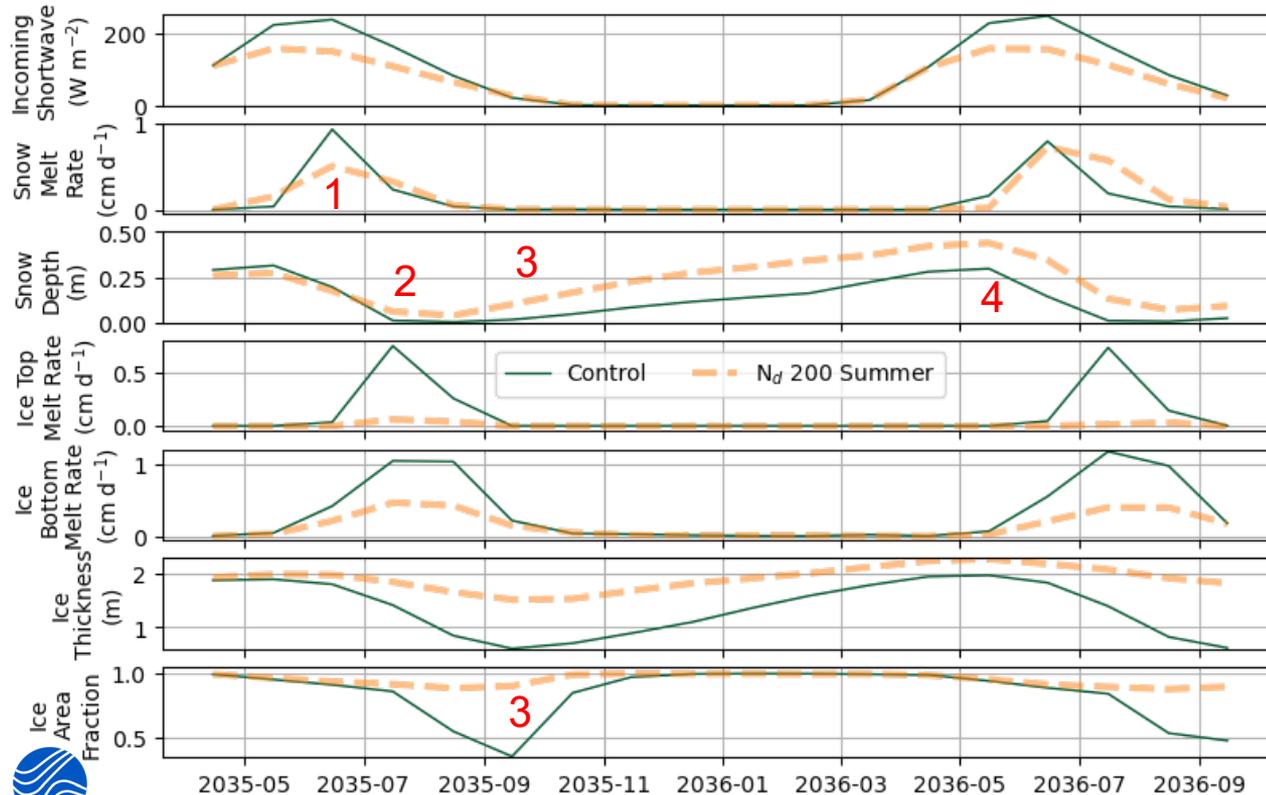

Temporal Evolution in Central Arctic

1. Incoming shortwave seasonally increases
2. Snow melts (~1 month after shortwave)
3. Ice top starts melting (~1 month after snow melt)

Temporal Evolution in Central Arctic

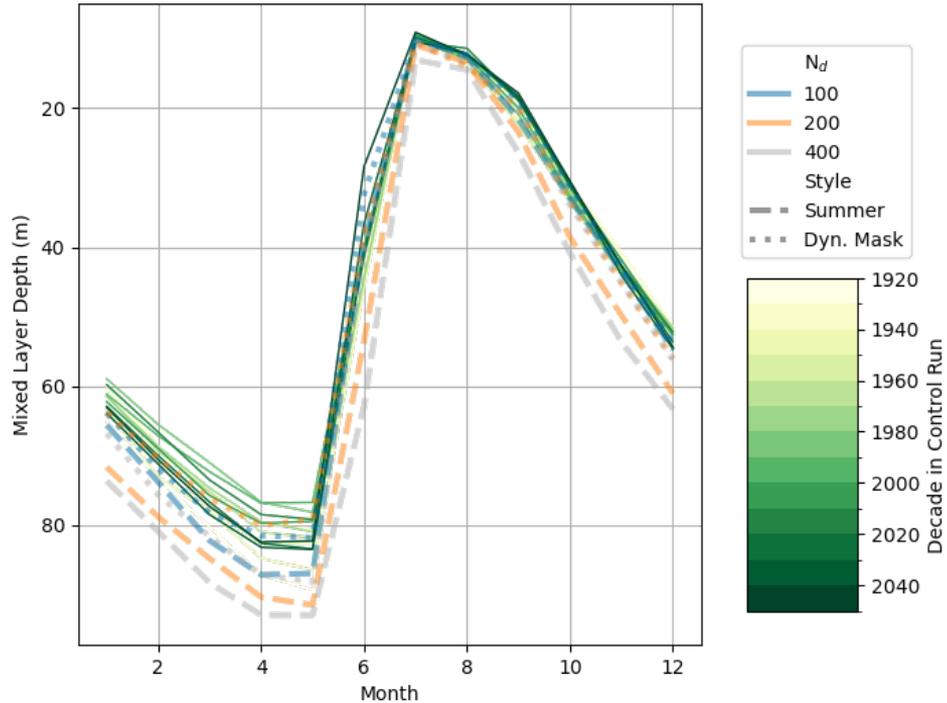

1. Snow melt rate is much lower
2. Snow persists through summer, shutting off ice top melt (also reduces bottom melt)
3. Persistent snow and more ice area in Fall lead to deeper snow throughout Fall and Winter
4. Following melt season starts with much deeper snow (interannual positive feedback)

Ocean Stratification Changes

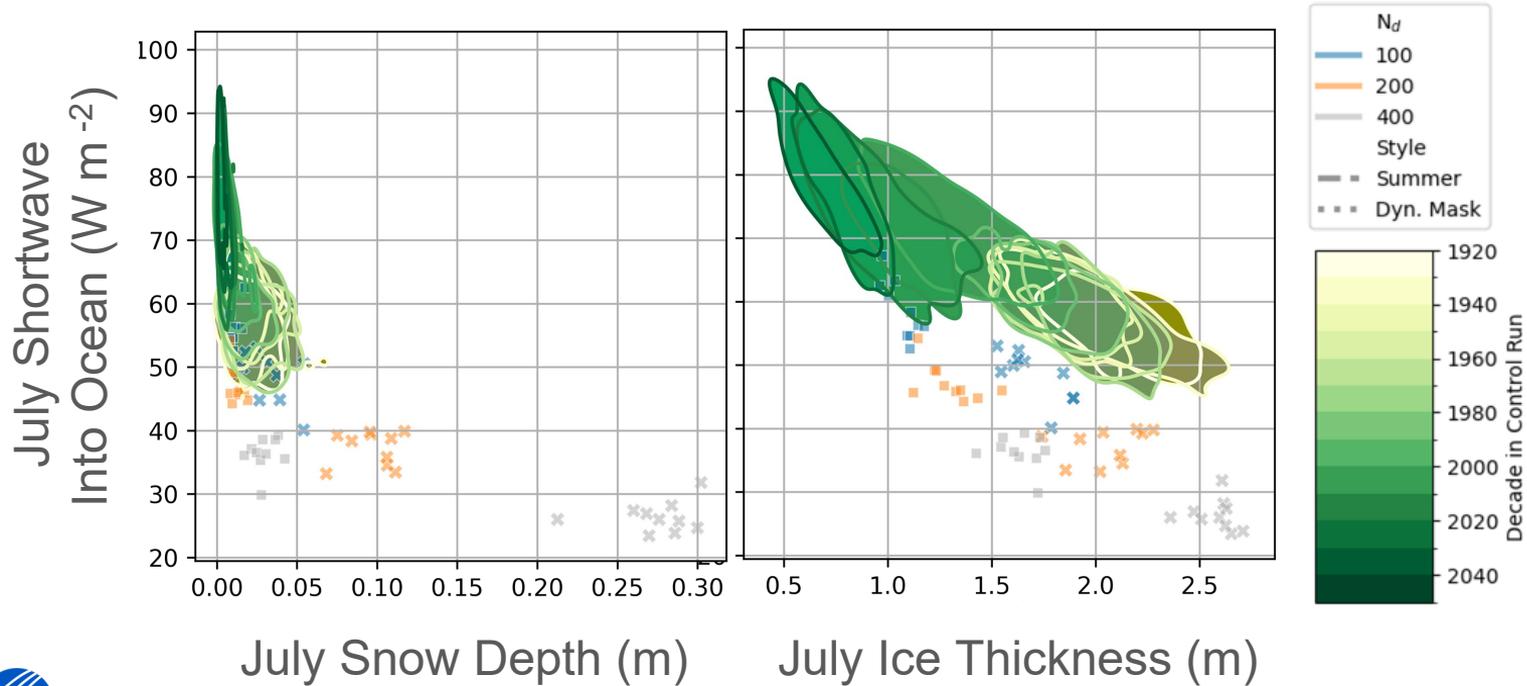

lat: 84.76, lon: 330.94

Ocean mixed layer in the Central Arctic in perturbed runs is generally deeper.

Especially in June, when seasonal shoaling due to freshwater from ice melt is delayed

Historically Unprecedented Low Light in Upper Ocean

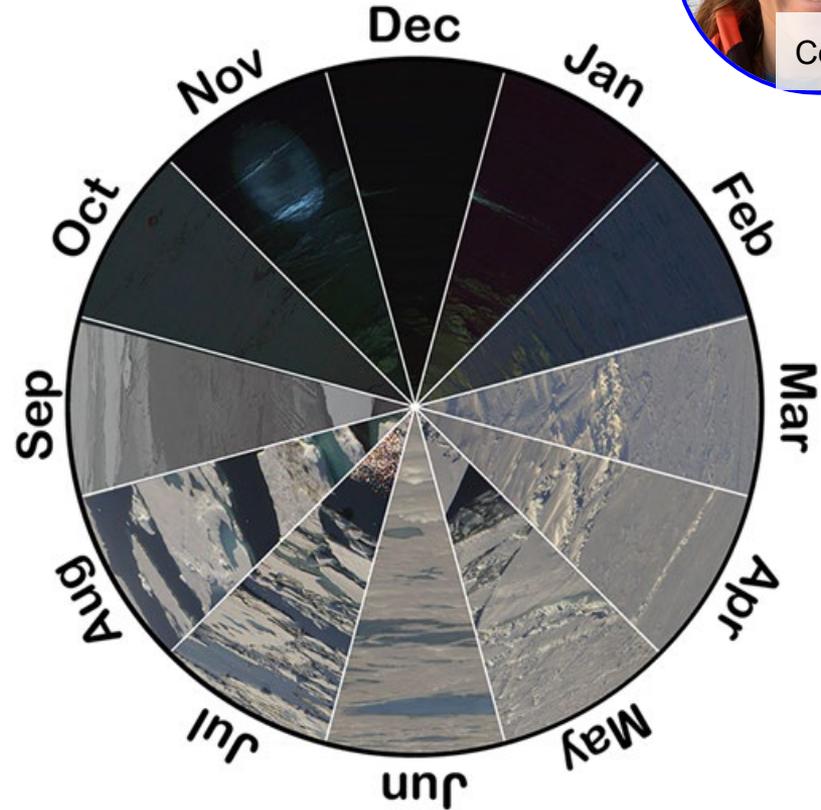

Snow, Sea Ice, & Ocean Impacts Takeaways

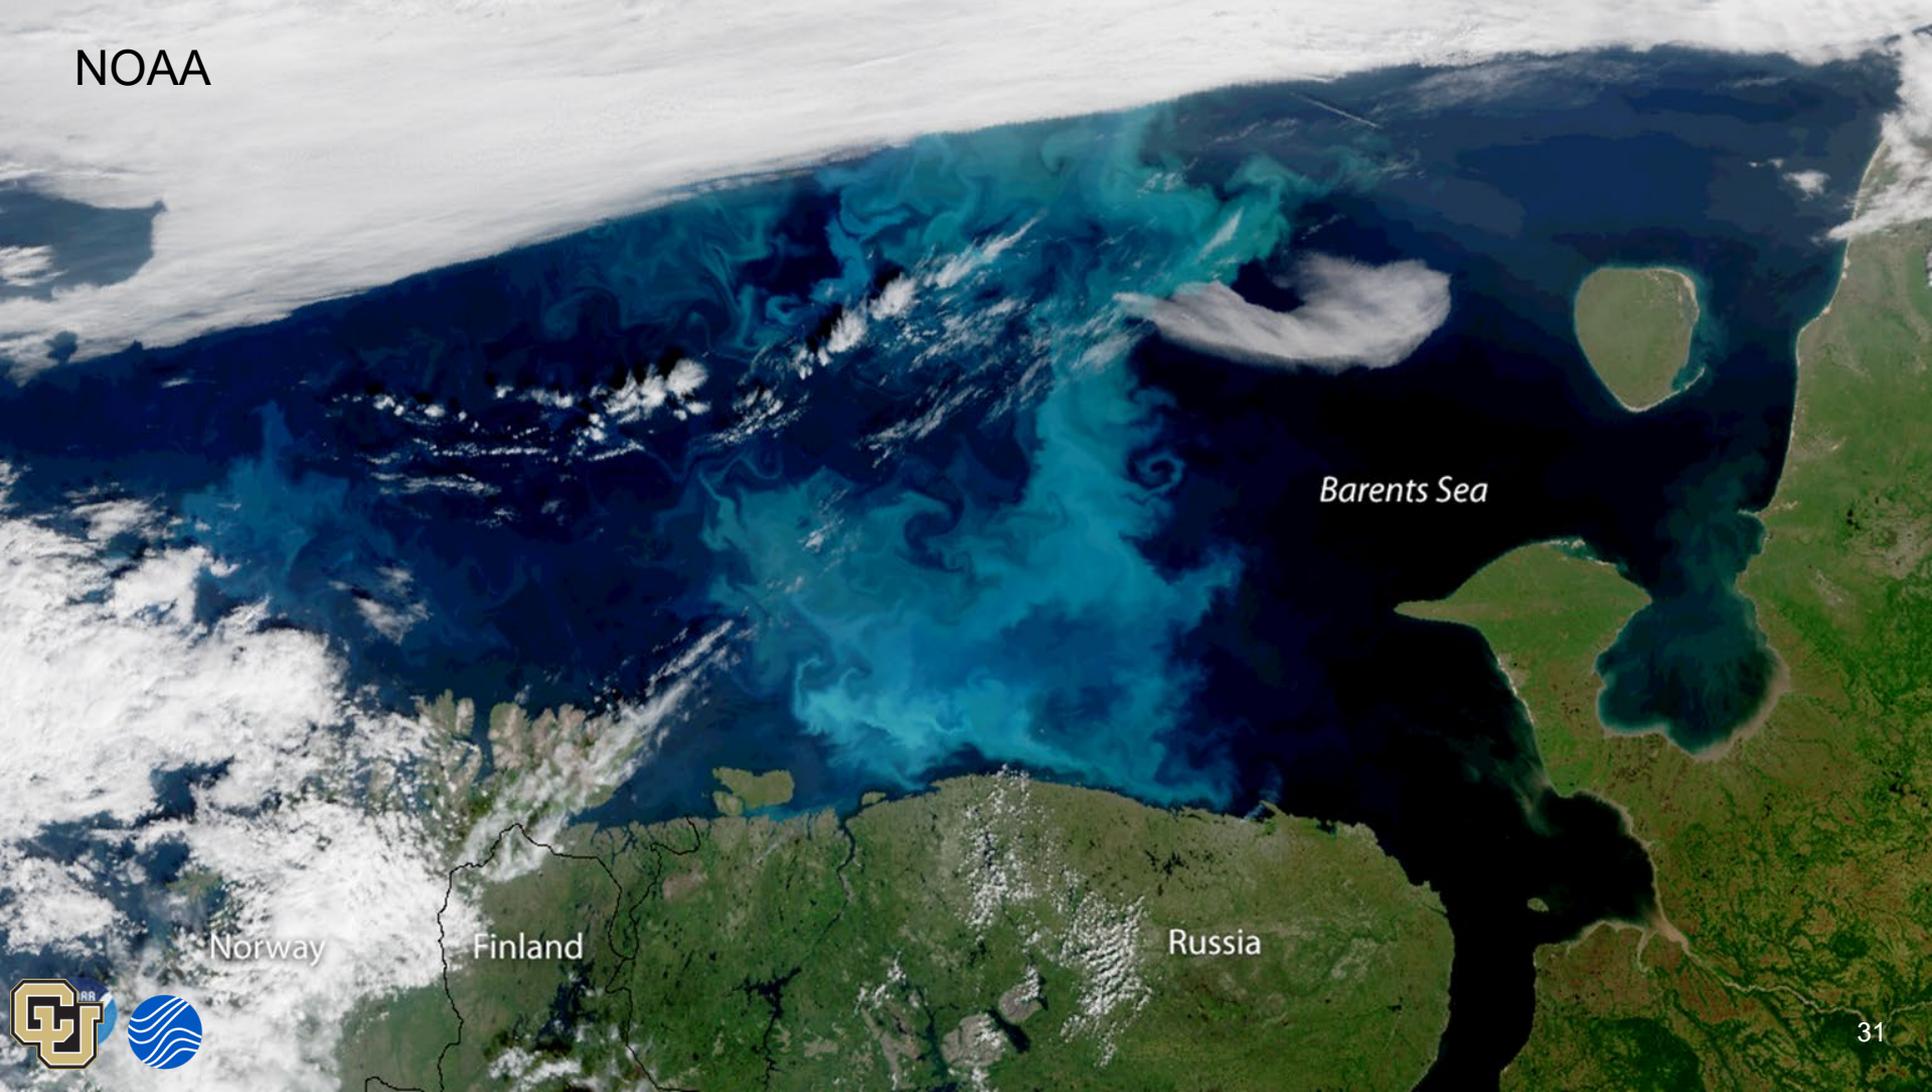

- Perturbations can cause decreases in summertime snow melt rates, resulting in historically-unprecedented perennial snow conditions.
- This produces a dampened annual cycle of ice melt and growth, which changes deepens and delays shoaling of the ocean mixed layer depth.
- Perennial snowpacks also produce historically-unprecedented low levels of sunlight in the upper ocean.

- Motivation
- Experimental Setup
- Global Impacts
- Atmospheric and Surface Energy Budget Impacts
- Snow, Sea Ice, & Ocean Impacts
- Ecosystem Impacts
- Conclusions and Next Steps

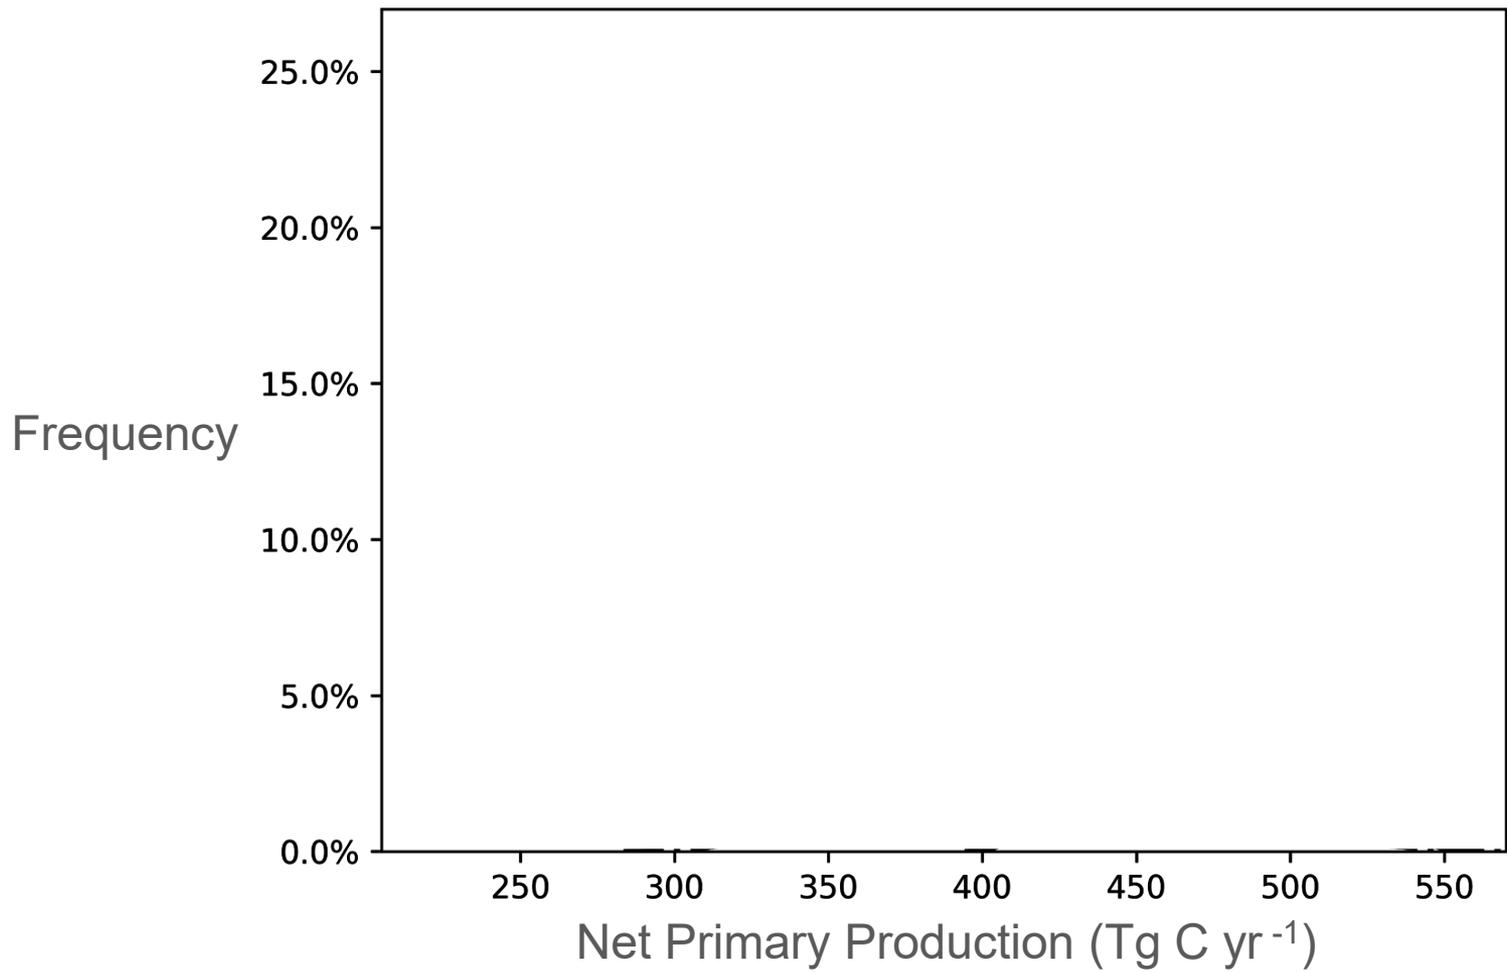

Barents Sea

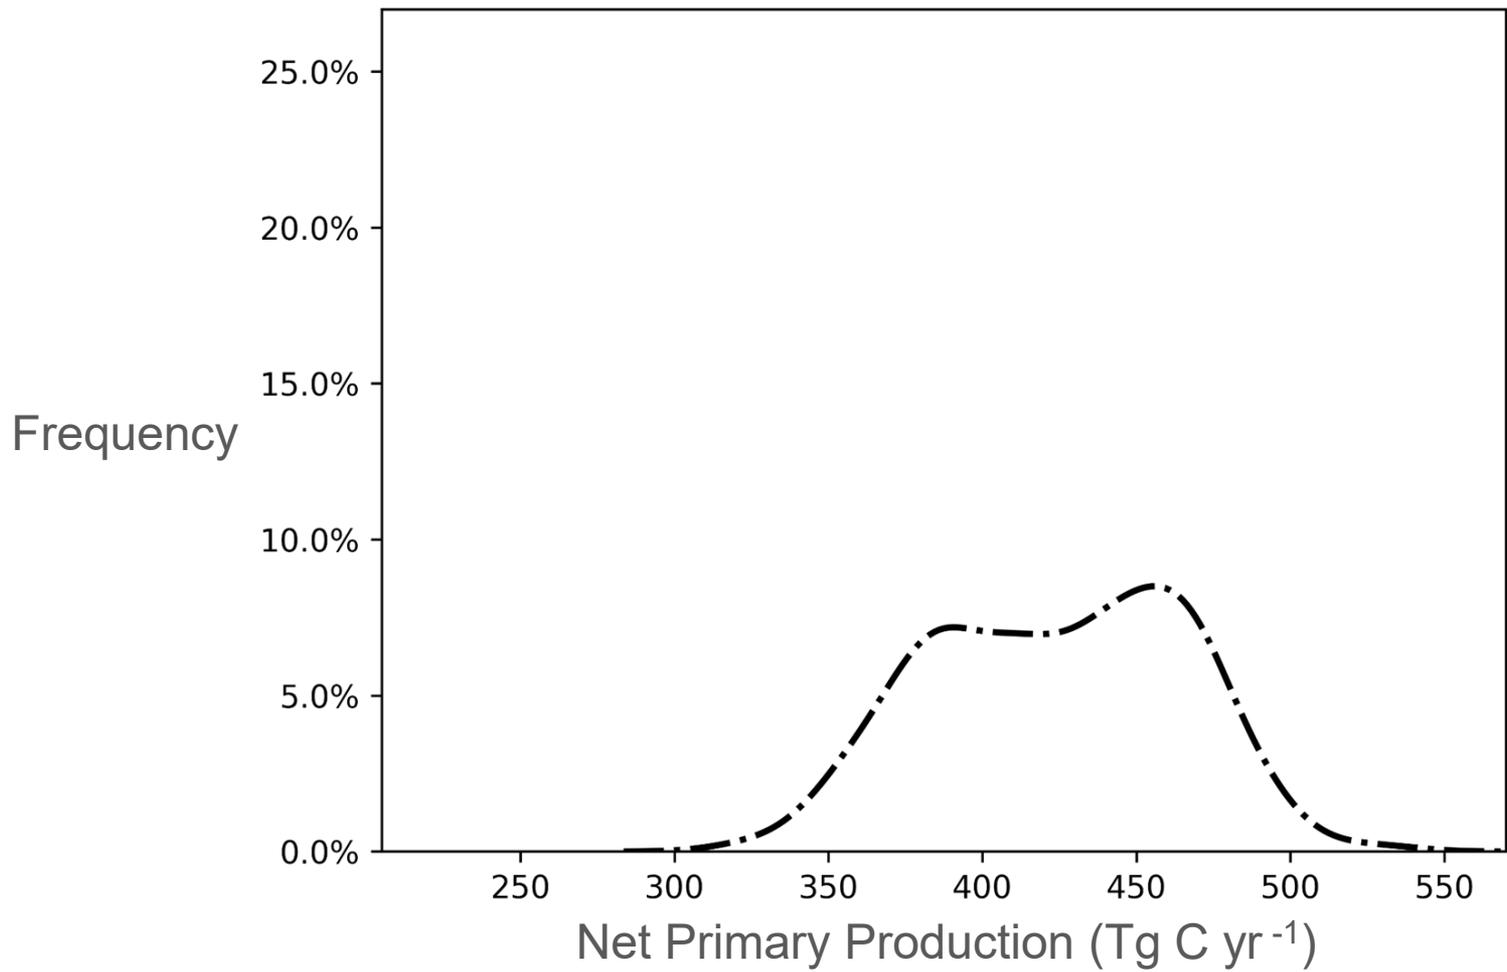

Norway

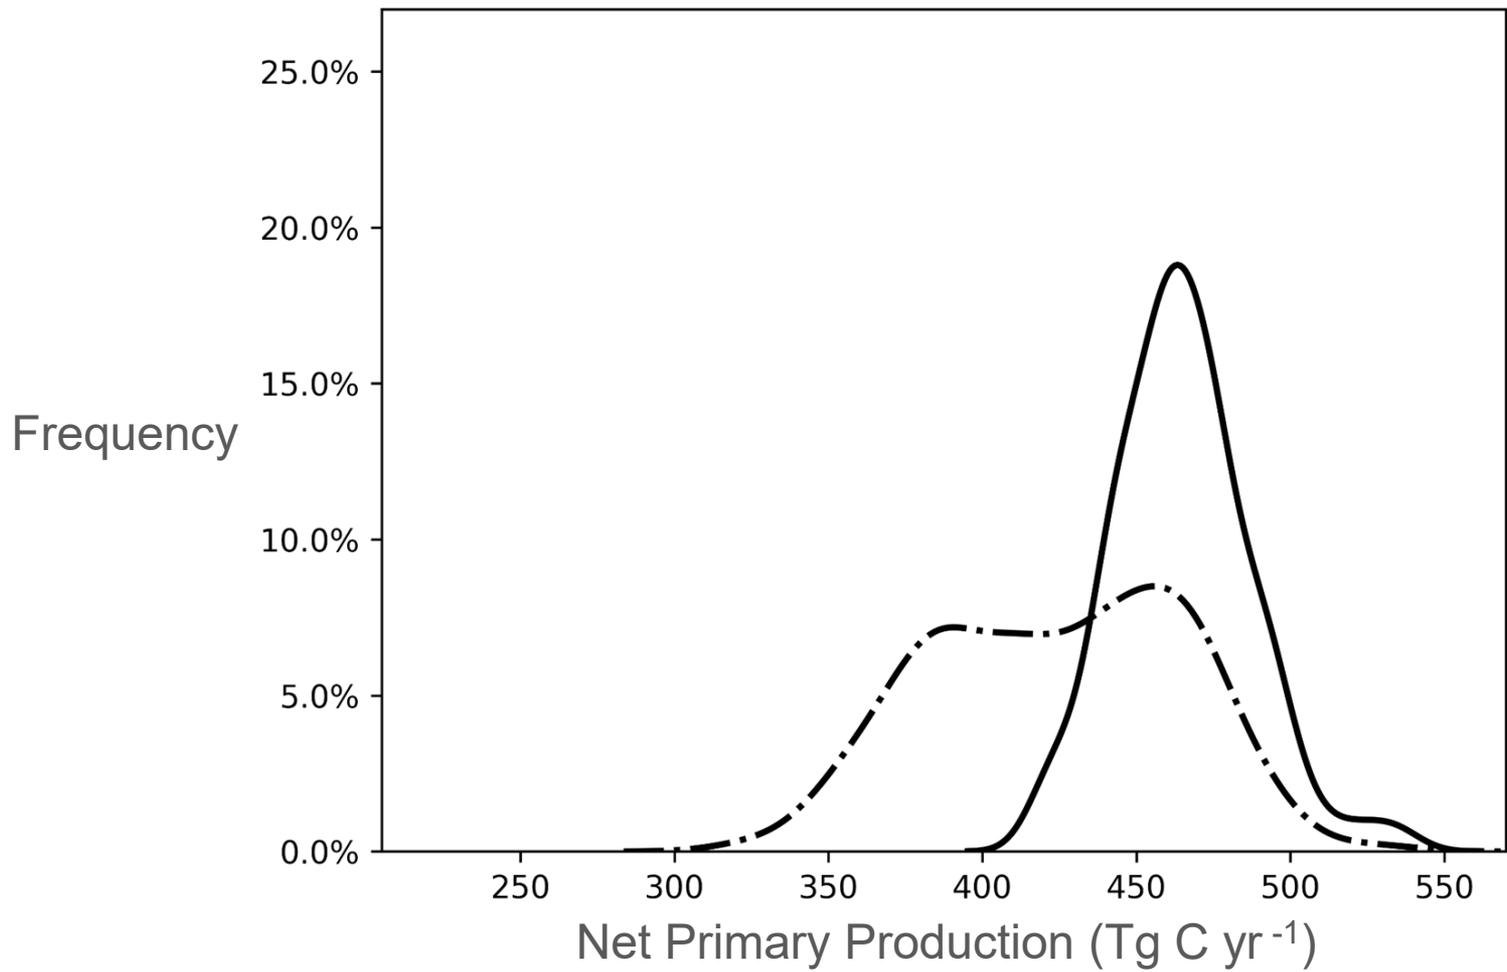

Finland

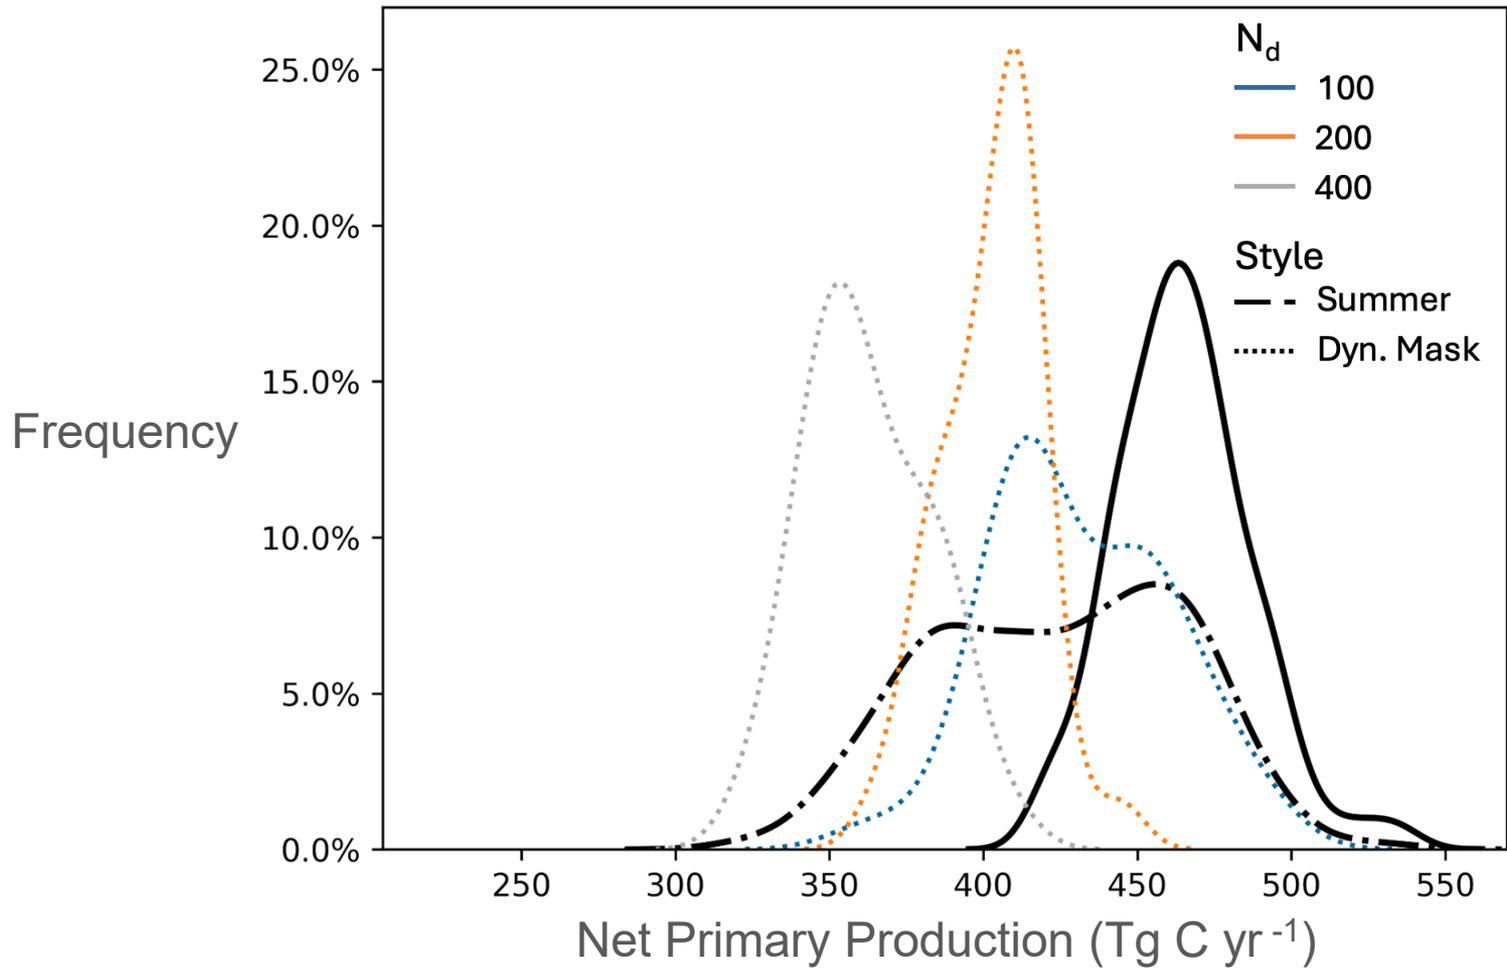

Russia

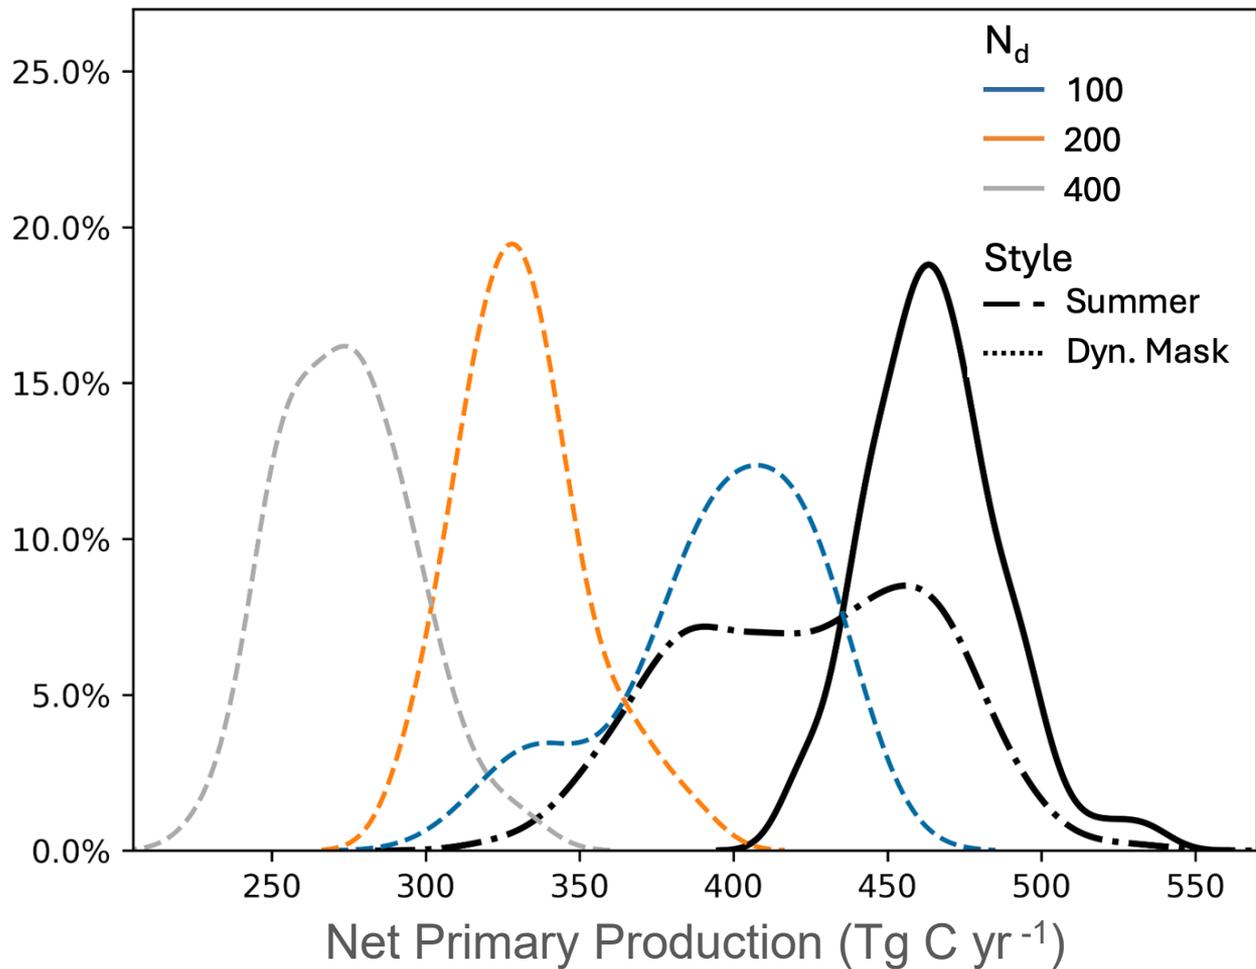

Perturbations significantly reduce Arctic NPP

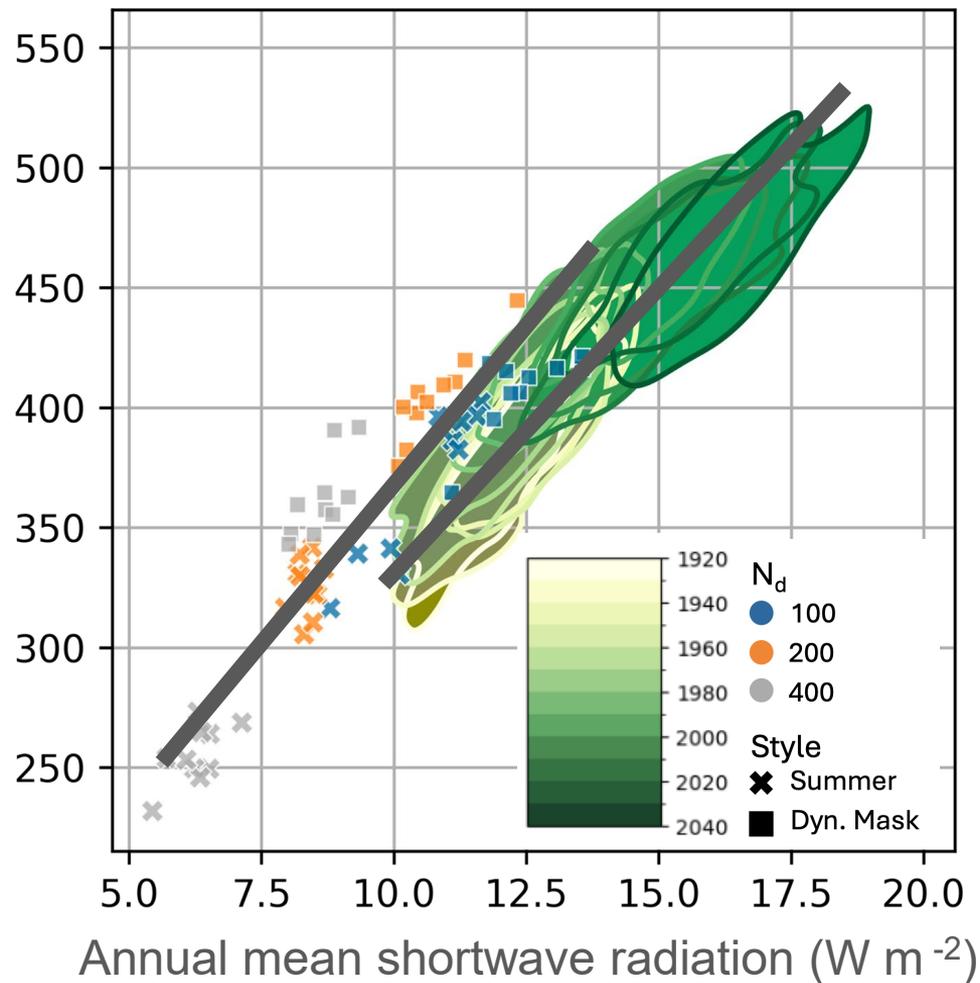

Frequency

Lower light conditions drive reduced NPP

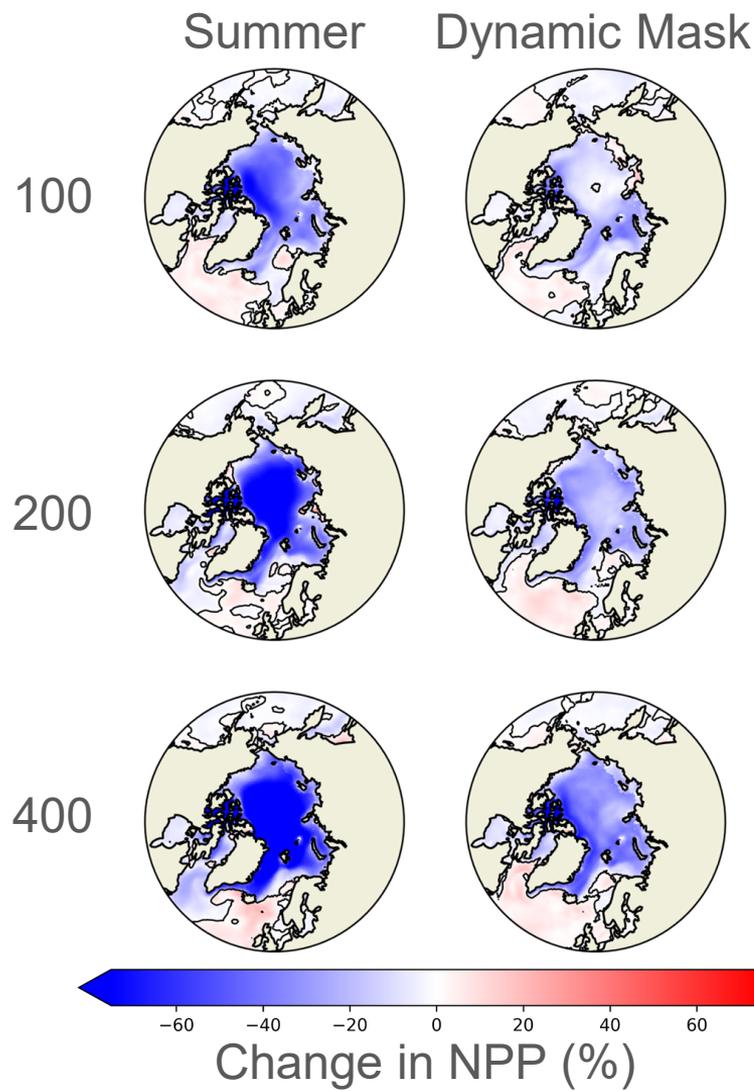

- Higher perturbed NPP at the same light level is likely due to changes in stratification

Annual Net Primary Production (Tg C yr^{-1})

Decline is focused in the central Arctic

- 15 - 82% decline in NPP north of 80°N relative to unperturbed simulations
- 8 - 39% decline in NPP within the Arctic Circle (>67°N)
- 3 - 9% decline in NPP over the Arctic and sub-Arctic (>50°N)

Marine Ecosystem Impacts Takeaways

- Marine cloud brightening perturbations can substantially dampen Arctic and sub-Arctic phytoplankton productivity.
- Changes in productivity are largely tied to reductions in light driven by increased snow thickness, particularly in the Central Arctic.
- Reduced productivity likely impacts regional C sequestration and food availability to marine ecosystems

Key Takeaways

- Summer perturbations over marginal ice zone and ocean are most efficient
- Unprecedented climate states in the snow/sea ice, upper ocean, and marine ecosystem

Next Steps

- Other Arctic impacts (permafrost, Greenland Ice Sheet, etc.)
- Impacts outside Arctic (midlatitude temperatures, tropical precipitation, AMOC, etc.)
- Explore in CESM3 with updated cloud liquid and ice physics and melt pond physics
